## Trigonal Pyramids: Alternative Ground-State Structures for Sixteen-Electron Complexes\*\*

Detlev Ostendorf, Clark Landis, and Hansjörg Grützmacher\*

It is widely believed that tetracoordinate complexes of d<sup>8</sup> transition metal centers (Rh<sup>I</sup>, Ir<sup>I</sup>, Pd<sup>II</sup>, Pt<sup>II</sup>, etc.) have a planar structure (P, ideal  $D_{4h}$  symmetry) and, indeed, hundreds of examples are known.<sup>[1]</sup> However, apart from tetrahedral structure T, which is observed for high-spin transition metals from the 4th period,<sup>[2]</sup> sawhorse (SH,  $C_{2\nu}$ ) and trigonal-pyramidal structures (TP,  $C_{3\nu}$ ) are alternatives (Scheme 1).<sup>[3]</sup>

**Scheme 1.** Planar (P), tetrahedral (T), sawhorse (SH), and trigonalplanar (TP) structures.

The highly reactive transient carbonyls  $[M(CO)_4]$  (M = Fe, Ru, Os) have SH structures,<sup>[4a-c]</sup> as do a few recently isolated Ru<sup>0</sup> and Rh<sup>I</sup> complexes, which show remarkable reactivity.<sup>[4d-f]</sup>

Even computationally, the TP structure has been rarely considered. Pidun and Frenking investigated by DFT methods [RhX(CO)<sub>3</sub>] complexes with X = H, HC=O, CH<sub>2</sub>OH, and OMe. For [Rh(HC=O)(CO)<sub>3</sub>], TP is the (slightly) preferred ground-state structure, whereas all other complexes have either a P or an SH form in the global minimum.<sup>[5]</sup> Within the complementary spherical electron density (CSED) model, Mingos identified SH and TP forms as the next best choices to planar structures for 16-electron complexes of late transition metals.<sup>[6]</sup> In computations using the orbital ranked symmetry analysis method (ORSAM), Bayse and Hall considered d<sup>8</sup>-MH<sub>4</sub> hydrides with SH and TP forms.<sup>[7]</sup> Proposals for making

the TP forms the ground-state structures have not been made. Herein we report the synthesis and isolation of stable compounds that have such a trigonal pyramidal structure.

What ligand set would make the trigonal pyramid the ground-state structure for an  $ML_4$  complex? We reasoned that such a structure might be obtained when the resonance form **A** contributes strongly to the electronic ground state with minimal participation of **B** (Scheme 2).

Scheme 2. Resonance structures A and B contributing to the electronic ground state of a TP structure.

This case arises when a formally d<sup>10</sup>-ML<sub>3</sub> donor fragment such as  $[Rh(C_2H_4)_3]^-$ , which is known to have a trigonalplanar structure,<sup>[8]</sup> is combined with a cation X<sup>+</sup>, most simply a proton or a silyl cation SiH<sub>3</sub><sup>+</sup>. Indeed, DFT calculations for  $[RhH(C_2H_4)_3]$  and  $[Rh(SiH_3)(C_2H_4)_3]$  show that the trigonalpyramidal form with H or SiH<sub>3</sub> in the apex is significantly more stable than the planar form (Table 1).<sup>[9]</sup>

 $\textit{Table 1:}\xspace$  Calculated relative energies of trigonal-pyramidal (TP) and planar (P) [RhXL\_3] complexes.  $^{[a]}$

[a] B3PW91 functional; 6-31 + G\* for non-metal atoms, LANL2DZ at Rh.

Remarkably, even when one  $\pi$ -acceptor  $C_2H_4$  ligand is replaced by a  $\sigma$ -donor PH<sub>3</sub> ligand, the TP form of [Rh(SiH<sub>3</sub>)-(PH<sub>3</sub>)(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>] is more stable (by about 11 kcal mol<sup>-1</sup>) than the planar *cis*-[Rh(SiH<sub>3</sub>)(PH<sub>3</sub>)(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>] complex.<sup>[10]</sup>

None of the species in Table 1 is likely be isolated, because insertion of a coordinated  $C_2H_4$  into the Rh–H or Rh–Si bond is expected (Rh<sup>I</sup> complexes are efficient catalysts for hydrogenation and hydrosilylation). Therefore we synthesized bis(5*H*-dibenzo[*a*,*d*]cyclohepten-5-yl)methylsilane (trop<sub>2</sub>Si-HMe, **2**), in which this insertion is unlikely to occur because of resulting strain energy in the product.<sup>[11]</sup> Silane **2** is easily obtained in 85% overall yield from 5-chloro-5*H*-dibenzo-[*a*,*d*]cycloheptene (tropCl, **1**), which was first metalated with elemental lithium and then coupled in situ with MeHSiCl<sub>2</sub> (Scheme 3).

Note that the rigid conformation of **2** will not allow for a planar structure, but a sawhorse type structure may be obtainable. Silane **2** was treated with 0.5 equiv of  $[Rh_2(\mu-Cl)_2(C_2H_4)_4]$  in chlorobenzene. Ethylene and HCl were liberated, and yellow crystals of  $[Rh(trop_2SiMe)-(C_2H_4)]\cdot C_6H_5Cl$  (**3**) precipitated in about 70% yield from

Scheme 3. Syntheses of silane 2 and complexes 3-5.

the reaction mixture. When the reaction was performed in THF, or complex **3** was recrystallized from THF,  $[Rh(trop_2SiMe)(C_2H_4)(thf)]$  (**4**) was obtained in 70% yield. Finally, when **3** was treated with one equivalent of PPh<sub>3</sub> in THF, ethylene evolved and yellow crystals of  $[Rh(trop_2SiMe)(PPh_3)]$  (**5**) were isolated in almost quantitative yield.

Single crystals of **3**, **4**, and **5** were investigated by X-ray diffraction<sup>[12]</sup> (Figures 1–3). Clearly, **3** has the predicted trigonal-pyramidal structure; the calculated and experimental data agree satisfactorily (see legend to Figure 1). The three coordinated C=C units lie in the basal plane and bind in a trigonal fashion to the Rh atom, which deviates slightly (0.125 Å) from the plane through ct1–ct3 towards the inside of the pyramid (Figure 1b). The ct-Rh-Si angles are close to 90°. In the crystal lattice, one molecule of chlorobenzene lies between two molecules of **3**, but the absence of contacts shorter than 3.63 Å rules out any bonding interaction.

The structural parameters of the core of **4** are very similar to those of **3**. The Rh<sup>1</sup> atom deviates by 0.085 Å from the plane through ct1–ct3 (Figure 2). A THF molecule binds loosely to the Rh<sup>1</sup> center and completes the trigonalbipyramidal coordination sphere typical of an 18-electron d<sup>8</sup>-ML<sub>5</sub> complex. The very long Rh<sup>1</sup>–O distance (2.544 Å) indicates a very weak interaction.

The crystal lattice of the phosphane silanide complex **5** contains no further solvent molecules, and the complex also has the predicted trigonal-pyramidal structure: The sum of the basal bond angles around the rhodium center is  $356.6^{\circ}$ . Like in **3** and **4**, the angles enclosed by the centroids of the coordinated C=C bonds and the apical Si atom are close to 90°. The ct-Rh-ct angle (129.6°) in **5** is somewhat wider than

Σ(ct-Rh-ct) = 359.5°; Σ(C-Si-C) = 320.9°. b) Plot of the core of **4**.

those in **3** and **4**, while the ct-Rh-P angles are slightly more acute (111.8, 115.2°). The Rh–Si bonds in **3** (2.236(1) and 2.266(2) Å), **4** (2.243(1) Å), and **5** (2.235(1) Å) are remarkably short, even shorter than the formal Rh=Si bonds in Rh<sup>I</sup> silylene complexes.<sup>[13a]</sup> The Rh–P distance of 2.335(1) Å lies within the upper range of Rh–P bond lengths (ca. 2.26–2.34 Å).<sup>[14]</sup>

All structural features of the core are well reflected by the computed data for the unconstrained model  $[Rh(SiH_3)(PH_3)(C_2H_4)_2]$  (see legend to Figure 3). Only the experimentally determined P-Rh-Si angle in 5 (103.4(1)°) is larger than the calculated one (91.1°), certainly due to steric interactions, which can also be made responsible for the larger displacement of the Rh center from the basal plane of 0.220 Å. The acute C38-P1-Rh1 angle (94.9(1)°), which is significantly smaller that the other two C-P-Rh angles (130.4° and 118.0°), is noteworthy. This distortion may indicate a positive hyperconjugative interaction of the P–C  $\sigma$  bond with the empty orbital at the Rh<sup>I</sup> center pointing outwards from the basal plane to the missing apical corner of a trigonal-bipyramidal (TBP) structure. Such distortions were also observed for complexes with SH-type structure, in which a P–C  $\sigma$  bond of an apically bonded PR<sub>3</sub> ligand may interact with an unfilled orbital pointing to the missing equatorial site of a TBP structure.<sup>[4d,e]</sup>

The NMR data of 3 and 5 are compatible with the structures observed in the solid state. In particular, the <sup>1</sup>H NOESY spectrum of 5 shows intense cross-peaks for the protons of the SiMe group and the phenyl protons of the PPh<sub>3</sub> ligand indicative of a cis arrangement. Such interactions are not expected for a compound in which the PPh<sub>3</sub> group is *trans* to the SiMe group. In the <sup>1</sup>H and <sup>13</sup>C NMR spectra of all reported compounds, the significant shift of the olefinic CH resonances to lower frequencies (coordination shifts  $\Delta \delta_{\text{coord}} = \delta_{\text{complex}} - \delta_{\text{ligand}}$ : <sup>1</sup>H: approx. -2 ppm, <sup>13</sup>C: approx. -60 ppm)<sup>[15]</sup> indicates significant metal-to-ligand backdonation. However, the inequivalent <sup>1</sup>H environments of the coordinated  $H_2C=CH_2$  molecule in **3** lead to a slightly broadened singlet at room temperature; even at low temperature (183 K) no sharp distinct signals were observed, and this indicates a rather low barrier for rotation around the Rh-ct3 axis.

The NMR data of **3** in  $CD_2Cl_2$  and of the THF complex **4** in  $[D_8]$ THF are almost identical. We therefore assume that the equilibrium **3** + THF $\rightleftharpoons$ **4** lies far to left and that the interaction of the rhodium center with a fifth ligand in the apical position *trans* to the Si atom is very weak. In particular, the <sup>29</sup>Si and <sup>103</sup>Rh NMR resonances, which one would expect to respond most sensitively to complexation of an additional fifth

Σ(ct-Rh-ct) = 356.6°; Σ(C-Si-C) = 322.7°. b) Plot of the core of **5.** Computed data for [Rh(SiH<sub>3</sub>)(PH<sub>3</sub>)(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>] (C<sub>2</sub>υ): Rh–Si 2.279, Rh–P 2.342, Rh–ct 2.051, Rh–C 2.158–2.180, C=C 1.410; P-Rh-Si 91.1, H-P-Rh 2×121.4, H-P-Rh 119.4, ct-Rh-ct 131.0, ct-Rh-P 114.2, Σ(ct-Rh-ct) = 359.5°; Σ(H-Si-H) = 319.4°.

ligand, do not differ much (3:  $\delta$ (<sup>29</sup>Si) = 100.4,  $\delta$ (<sup>103</sup>Rh) = -712.6; 4:  $\delta(^{29}\text{Si}) = 97.15$ ,  $\delta(^{103}\text{Rh}) = -654.5$ ]. Furthermore, no cross-peaks between the olefinic protons and  $\alpha$ -CH<sub>2</sub> protons of the THF molecule were observed. These observations are in line with predictions made with the CSED model and the general expectations for the trans influence: The LUMO of a trigonal-pyramidal d<sup>8</sup>-ML<sub>4</sub> complex is rather high in energy and "unavailable" for binding of a nucleophile.<sup>[6]</sup> Note, however, that planar  $d^8$ -ML<sub>4</sub> complexes are even more reluctant to interact with nucleophiles when a distortion from planarity is suppressed. Furthermore, trigonal-bipyramidal d<sup>8</sup>-ML<sub>5</sub> complexes, conventionally obtained from planar d<sup>8</sup>-ML<sub>4</sub>, have the kinetically labile ligand in an equatorial position. Those obtained from TP complexes show lability in the axial position. The remarkable high-frequency shifts of the <sup>29</sup>Si NMR resonances in **3–5** (ca. +100 ppm vs. -10.4 ppm in 2) would be formally in accord with a high weight of resonance structure A (Scheme 1) but should not be overinterpreted.

Finally, a cyclic voltammogram of **3** in THF with 0.1 m  $n \text{Bu}_4 \text{NPF}_6$  showed one irreversible oxidation wave at +0.6 V and two irreversible reduction waves at -3.1 and -3.3 V versus ferrocenium/ferrocene. This demonstrates the high thermodynamic stability of the neutral molecule with a trigonal-pyramidal structure with respect to its cation and anion, respectively.

Clearly, the trigonal-pyramidal form is a possible ground state structure for  $d^8$ -ML<sub>4</sub> complexes. Our investigations indicate that a ligand set composed of at least one very strong (H, SiR<sub>3</sub>) and two very weak  $\sigma$ -donor but good  $\pi$ -acceptors

(olefins) favors the TP form. A deeper investigation of the electronic structure and factors that stabilize trigonalpyramidal molecules as well as their potential use as Lewis acids with a well-defined rigid structure<sup>[16]</sup> is underway.

### **Experimental Section**

All syntheses were performed under an atmosphere of argon by using standard Schlenk techniques. Details of the syntheses and a complete listing of spectroscopic data are given in the Supporting Information.

2: A slight excess of lithium powder (0.310 g, 44.7 mmol) was added to a solution of  $\mathbf{1}^{[17]}$  (5.00 g, 22.1 mmol) in THF (25 mL) at -78 °C. The mixture was stirred for 30 min at 0 °C and for 2 h at room temperature. The resulting deep red solution was added to a solution of dichloromethylsilane (1.26 g, 11.0 mmol) in THF (20 mL) at 0 °C. After stirring overnight, all volatile compounds were evaporated; the residue was taken up in 50 mL of toluene, the suspension filtered, and **2** was isolated from the filtrate as a pale yellow solid which was used without further purification. Yield: 4.07 g (9.5 mmol, 86 %). M.p. 58 °C. <sup>1</sup>H NMR (500.2 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -0.27$  (d,  ${}^{3}J_{\text{HH}} = 3.6$  Hz, 3 H; CH<sub>3</sub>), 4.28 (m, 1 H; SiH), 6.65 (d,  ${}^{3}J_{\text{HH}} = 11.9$  Hz, 2 H; CH<sub>olefin</sub>).  ${}^{13}C$  NMR (125.8 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -3.20$  (s, 1 C; CH<sub>3</sub>), 132.69 (s, 2 C; CH<sub>olefin</sub>), 133.09 ppm (s, 2 C; CH<sub>olefin</sub>).  ${}^{29}$ Si NMR (99.4 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -10.44$  ppm.

**3**:  $[Rh_2(\mu_2-Cl)_2(C_2H_4)_4]$  (46 mg, 0.117 mmol) and **2** (100 mg, 0.234 mmol) were dissolved in chlorobenzene (1 mL) at 0 °C. After 20 min the color of the reaction mixture had changed from bright orange to brownish yellow. Over 4 d at -20 °C pale yellow

crystals of **3** formed. Yield: 109 mg (0.171 mmol, 70%). M.p. > 124 °C (decomp.). <sup>1</sup>H NMR (500.2 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -0.93$  (s, 3H; CH<sub>3</sub>), 4.72 (d, <sup>3</sup>*J*<sub>HH</sub> = 10.5 Hz, 2H; CH<sub>olefin</sub>). <sup>4.9</sup>A ppm (d, <sup>3</sup>*J*<sub>HH</sub> = 10.5 Hz, 2H; CH<sub>olefin</sub>). <sup>13</sup>C NMR (125.8 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -4.78$  (s, 1C; CH<sub>3</sub>), 70.12 (d, <sup>1</sup>*J*<sub>RhC</sub> = 6.7 Hz, 2C; CH<sub>olefin</sub>), 71.00 (s, 2C; CH<sub>ethylen</sub>), 73.92 ppm (d, <sup>1</sup>*J*<sub>RhC</sub> = 8.2 Hz, 2C; CH<sub>olefin</sub>). <sup>29</sup>Si NMR (99.4 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -100.35$  ppm (d, <sup>1</sup>*J*<sub>RhSi</sub> = 45.3 Hz). <sup>103</sup>Rh NMR (15.8 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = -712.58$  ppm (s).

4: [Rh<sub>2</sub>(μ<sub>2</sub>-Cl)<sub>2</sub>(C<sub>2</sub>H<sub>4</sub>)<sub>4</sub>] (46 mg, 0.117 mmol) and **2** (100 mg, 0.234 mmol) were dissolved in THF (1 mL) at room temperature. Gas evolution (C<sub>2</sub>H<sub>4</sub>) was observed and after 5 min the solution was concentrated to 0.5 mL, shortly warmed to about 40 °C, and cooled to room temperature. Pale yellow crystals of **4** began to precipitate, and the mixture was stored at 7 °C for 10 d. Yield: 70 % (103 mg, 0.164 mmol). M.p. > 178 °C (decomp). <sup>1</sup>H NMR (500.2 MHz, 263 K, [D<sub>8</sub>]THF):  $\delta = -1.07$  (s, 3H; CH<sub>3</sub>), 3.02 (s, 4H; CH<sub>ethylene</sub>), 4.68 (d, <sup>3</sup>J<sub>HH</sub> = 10.4 Hz, 2H; CH<sub>olefin</sub>), 4.87 ppm (d, <sup>3</sup>J<sub>HH</sub> = 10.4 Hz; 2H, CH<sub>olefin</sub>). <sup>13</sup>C NMR (125.8 MHz, 263 K, [D<sub>8</sub>]THF):  $\delta = -6.26$  (s, 1C; CH<sub>3</sub>), 69.46 (d, <sup>1</sup>J<sub>RhC</sub> = 6.7 Hz, 2C; CH<sub>2,ethylene</sub>), 69.49 (d, <sup>1</sup>J<sub>RhC</sub> = 6.7 Hz, 2C; CH<sub>olefin</sub>), 72.85 ppm (d, <sup>1</sup>J<sub>RhC</sub> = 7.9 Hz, 2C; CH<sub>olefin</sub>). <sup>29</sup>Si NMR (99.4 MHz, [D<sub>8</sub>]THF):  $\delta = -654.54$  ppm.

5: 4 (55 mg, 0.087 mmol) was treated with triphenylphosphane (23 mg, 0.088 mmol) in THF (1 mL) at room temperature. Ethylene evolution was observed and after 5 min the solution was layered with hexane (1 mL) and cooled to -15 °C. Yellow crystals of **5** were isolated by filtration and dried in vacuo (67 mg, 0.085 mmol, 97%). M.p. > 161 °C (decomp). <sup>1</sup>H NMR (500.2 MHz, [D<sub>8</sub>]THF):  $\delta = -0.28$  (d, <sup>4</sup>*J*<sub>PH</sub> = 2.8 Hz, 3H; CH<sub>3</sub>), 3.86 (m, 2H; CH<sub>olefin</sub>), 4.29 ppm (m, 2H; CH<sub>olefin</sub>). <sup>13</sup>C NMR (100.6 MHz, [D<sub>8</sub>]THF):  $\delta = 1.75$  (dd, <sup>3</sup>*J*<sub>CP</sub> = 10.6 Hz, <sup>2</sup>*J*<sub>CRh</sub> = 1.5 Hz, 1 C; CH<sub>3</sub>), 65.97 (dd, <sup>1</sup>*J*<sub>CRh</sub> = 8.6 Hz, <sup>2</sup>*J*<sub>CP</sub> = 4.7 Hz, 2 C; CH<sub>olefin</sub>), 70.74 ppm (dd, <sup>1</sup>*J*<sub>CRh</sub> = 12.6 Hz, <sup>2</sup>*J*<sub>CP</sub> = 9.0 Hz, 2C; CH<sub>olefin</sub>). <sup>31</sup>P NMR (161.9 MHz, [D<sub>8</sub>]THF):  $\delta = 17.5$  (dz, <sup>1</sup>*J*<sub>SiR</sub> = 47.6 Hz, <sup>2</sup>*J*<sub>SiP</sub> = 5.8 Hz). <sup>31</sup>P NMR (161.9 MHz, [D<sub>8</sub>]THF):  $\delta = 17.5$  (dz, <sup>1</sup>*J*<sub>SiR</sub> = 5.8 Hz).

30.90 ppm (d,  ${}^{1}J_{PRh} = 138.6$  Hz).  ${}^{103}$ Rh NMR (12.6 MHz, [D<sub>8</sub>]THF):  $\delta = -484.14$  ppm (d,  ${}^{1}J_{PRh} = 139.0$  Hz).

J.* **2002**, *8*, 601, and references therein; b) for tetrahedral Ni<sup>II</sup> complexes, see: C. O. Dietrich-Buchecker, J. Guilhem, J.-M. Kern, C. Pascard, J.-P. Sauvage, *Inorg. Chem.* **1994**, *33*, 3498, and references therein.
- [3] We refer to trigonal pyramids as structures in which the angles between the axial and equatorial ligands are equal or close to 90°. Alternatively, they may be described as trigonal bipyramids in which one axial coordination site is vacant. A referee brought to our attention that MS<sub>3</sub>(L) fragments (M = V, Mo, Fe) with TP structures were observed in transition metal sulfide clusters: a) I. Noda, B. S. Snyder, R. H. Holm, *Inorg. Chem.* **1986**, *25*, 3851; b) E. Nordlander, S. C. Lee, W. C. Cen, Z. Y. Wu, C. R. Natoli, A. Di Cicco, A. Filipponi, B. Hedman, K. O. Hodgson, R. H. Holm, *J. Am. Chem. Soc.* **1993**, *115*, 5549.

- [9] All DFT calculations were carried out with the Gaussian 03 set of programs and the B3PW91 functional (for details see Supporting Information). For  $[Rh(SiH_3)(C_2H_4)_3]$ , the isomer with the SiH<sub>3</sub> group in the basal plane is less stable by 14 kcalmol<sup>-1</sup> and corresponds more to an alkyl complex  $[Rh(CH_2CH_2SiH_3)(C_2H_4)_2]$ , that is, one ethylene ligand has inserted into the Rh–Si bond. For  $[Rh(SiH_3)(PH_3)(C_2H_4)_2]$  no energy minimum for an isomer with a basal SiH<sub>3</sub> group was found.
- [10] The isomer with the SiH<sub>3</sub> and PH<sub>3</sub> groups in *trans* positions adopts a SH-type structure which is almost equal in energy to the planar *cis* form ( $\Delta E = -0.03 \text{ kcal mol}^{-1}$ ).
- [11] The synthesis of the related dibenzophosphasemibullvalene was recently reported: J. Geier, G. Frison, H. Grützmacher, Angew. Chem. 2003, 115, 4085; Angew. Chem. Int. Ed. 2003, 42, 3955.
- [12] Pale yellow, air-sensitive single crystals of **3** were obtained from chlorobenzene solution at -15 °C. Crystal data: C<sub>39</sub>H<sub>34</sub>ClRhSi; monoclinic; space group *P*2(1)/*c*; *a* = 10.6913(5), *b* = 11.5133(6), *c* = 24.6594(12) Å; *V* = 3020.2(3) Å<sup>3</sup>; *Z* = 4;  $\rho_{calcd} =$

1.437 Mg m<sup>-3</sup>; crystal dimensions  $0.36 \times 0.20 \times 0.11$  mm; Bruker SMART Apex diffractometer with CCD area detector; MoKa radiation ( $\lambda = 0.71073$  Å), 200 K, 2 $\Theta_{max} = 56.56^{\circ}$ ; 30672 reflections, 7483 independent ( $R_{int} = 0.0249$ ); direct methods; empirical absorption correction with SADABS (version 2.03); refinement against full matrix (versus  $F^2$ ) with SHELXTL (version 6.12) and SHELXL-97 (G. M. Sheldrick, Göttingen, 1997); 291 parameters, R1 = 0.0390 and wR2 (all data) = 0.1107, max./min. residual electron density 0.908/-0.473 e Å<sup>-3</sup>. All non-hydrogen atoms were refined anisotropically. The contribution of the hydrogen atoms in their calculated positions was included in the refinement by using a riding model. The chlorobenzene units and the units of 3 show an alternating alignment. Furthermore, four percent of the molecules of 3 are disordered about a mirror plane perpendicular to the Rh-Si1 bond (Rh1A-Si1A). The remaining atoms of the disordered molecules overlap with the ligand atoms of the main structure and could therefore not be localized. Pale yellow, air-sensitive single crystals of 4 were obtained from a solution in THF at room temperature. Crystal data: C<sub>37</sub>H<sub>37</sub>OSiRh; orthorhombic; space group P2(1)2(1)2(1);  $a = 10.9270(5), \quad b = 12.2839(6),$ c = 21.6322(10) Å;  $V \equiv$ 2903.6(2) Å<sup>3</sup>; Z = 4;  $\rho_{calcd} = 1.438 \text{ Mgm}^{-3}$ ; crystal dimensions  $0.24 \times 0.19 \times 0.15$  mm; Bruker SMART Apex diffractometer with CCD area detector;  $Mo_{K\alpha}$  radiation ( $\lambda = 0.71073$  Å), 200 K,  $2\Theta_{\text{max}} = 56.62^{\circ}$ ; 30385 reflections, 7220 independent ( $R_{\text{int}} =$ 0.0388); direct methods; refinement against full matrix (versus  $F^2$ ) with SHELXTL (version 6.12) and SHELXL-97; 362 parameters, R1 = 0.0280 and wR2 (all data) = 0.0626, max./min. residual electron density 0.930/-0.378 e Å<sup>-3</sup>. All non-hydrogen atoms were refined anisotropically. The contribution of the hydrogen atoms in their calculated positions was included in the refinement by using a riding model. Yellow, air-sensitive single plates of 5 were obtained from a solution in THF layered with nhexane at 7°C. Crystal data: C49H40SiPRh; monoclinic; space group P2(1)/c; a = 17.0615(8), b = 10.3224(5), c = 22.1621(11) Å;  $V = 3778.5(3) \text{ Å}^3; Z = 4; \rho_{\text{calcd}} = 1.390 \text{ Mg m}^{-3};$  crystal dimensions 0.30 × 0.22 × 0.06 mm; Bruker SMART K1 diffractometer with CCD area detector;  $Mo_{K\alpha}$  radiation ( $\lambda = 0.71073$  Å), 200 K,  $2\Theta_{\text{max}} = 52.75^{\circ}$ ; 30210 reflections, 7723 independent ( $R_{\text{int}} =$ 0.0447); direct methods; empirical absorption correction with SADABS (version 2.03); refinement against full matrix (versus  $F^2$ ) with SHELXTL (version 6.12) and SHELXL-97; 476 parameters, R1 = 0.0327 and wR2 (all data) = 0.0799, max./min. residual electron density  $0.754/-0.463 \text{ e} \text{ Å}^{-3}$ . All non-hydrogen atoms were refined anisotropically. The contribution of the hydrogen atoms in their calculated positions was included in the refinement by using a riding model. CCDC-602113 (3), -602114 (4), and -602115 (5) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data\_request/cif.

- [13] To date, 71 compounds with an Rh–Si bond are listed in the CCDC data base. For recent examples with Rh<sup>I</sup>–Si bonds, see:
