Received October 5, 2004

Treatment of a three-membered metallacycle $\operatorname{Cp}^*(\operatorname{CO})\operatorname{Fe}\{\kappa^2(Si,P)-\operatorname{SiMe}_2\operatorname{PPh}_2\}$ (1) with substrates of the type R_nEH (ER_n = OH, OMe, O'Bu, OPh, S'Tol, NEt₂, NPhH, PPh₂, and PPhH) results in the instantaneous formation of the ring-opening products Cp*(CO)Fe-(PPh₂H)(SiMe₂ER_n). In these reactions, 1,2-addition of the substrates occurs exclusively across the silicon-phosphorus bond in 1. The structures of the products have been unequivocally determined by spectroscopic data and X-ray diffraction analysis.

Introduction

Three-membered cyclic compounds with ring constituents of silicon and transition metal atoms have attracted much attention with respect to bonding modes and reactivity. Although several silametallacyclopropanes have been prepared and their reactivity toward various substrates has been investigated, there have been only limited studies concerning the reactions between silametallacyclopropane and substrates with E-H single bonds (E = typical elements having nonbonding electron pairs). Berry² and Tilley³ independently reported that the treatment of silene complexes, $L_nM\{\kappa^2(C,Si)\text{-CH}_2\text{-}$ SiR_2 (L_nM = Cp₂W, Cp*(PMe₃)Ir), with MeOH leads to the selective cleavage of the metal-silicon bonds to give $L_n(H)MCH_2Si(OMe)R_2$. Similarly, the disilene platinum complex $(Et_3P)_2Pt\{\kappa^2(Si,Si)-Mes_2SiSiMes_2\}$ has been shown to react with MeOH to give (Et₃P)₂Pt(H)-SiMes₂SiMes₂OMe through cleavage of the platinum silicon bond,⁴ while the disilene molybdenum complex $Cp_2Mo\{\kappa^2(Si,Si)-Me_2SiSiMe_2\}$ reacts with MeOH to give a mixture of Cp2Mo(H)SiMe2SiMe2OMe and Cp2Mo-(SiMe₂OMe)SiMe₂H in a 2:8 molar ratio by 1,2-MeOH addition to the silicon-silicon bond.⁵

Recently, our research has been focused on the synthesis and properties of three-membered metallacycles of the type $L_nM\{\kappa^2(Si,E)\text{-SiMe}_2ER_n\}$, in which the heteroatom (E) has at least one lone pair and the $\kappa^2(Si,E)$ -SiMe₂ER_n ligand donates three electrons in total to the metal center. 6 Our previous communication described the isolation of phosphasilametallacyclopropane, $Cp*(CO)Fe{\kappa^2(Si,P)-SiMe_2PPh_2}$ (1),^{6b} which exhibits unique reactivity toward molecules with a polarized unsaturated bond. For example, treatment of 1 with acetone led to insertion of the CO double bond into the silicon—phosphorus bond to produce $Cp^*(CO)Fe\{\kappa^2(Si,P)-$ SiMe₂OCMe₂PPh₂}. A heteroaromatic compound, 4-(dimethylamino)pyridine (DMAP), also reacted with 1 to give the insertion product. The present report examines the reactivity of 1 toward molecules with polarized E-H single bonds (E = O, N, S, P) such as water, alcohol, phenol, secondary amine, aniline, thiol, and primary and secondary phosphines. All reactions proceeded guickly at room temperature to give the 1,2-addition products through cleavage of the silicon-phosphorus bond.

Results and Discussion

Reactions of 1 with H₂O, MeOH, ^tBuOH, PhOH, ^pTolSH, Et₂NH, and PhNH₂. The reactions of 1 with R_nE-H (E = O, S, and N) are illustrated in Scheme 1. Selected infrared (IR) and nuclear magnetic resonance (NMR) data for complexes 1-8 are listed in Table 1. In the reactions of 1 with water, alcohols, and phenol at room temperature, the ring-opening products 2-5 were formed immediately and exclusively through cleavage of the silicon-phosphorus bond. The difference between the reaction mode between 1 and silene^{2,3} or disilene^{4,5} complexes toward MeOH is likely to reflect the highly polarized silicon-phosphorus bond. Complex 1 also reacted with PTolSH, Et2NH, and aniline to give the corresponding products 6-8 under the same reaction conditions.

Pham and West reported the reaction of the disilene complex (dppe)Pt{ $\kappa^2(\bar{S}i,Si)$ -Me $_2$ SiSiMe $_2$ } with ammonia to give (dppe)Pt{ $\kappa^2(Si,Si)$ -SiMe₂N(H)SiMe₂} in nearly

quantitative yield.⁴ Although the authors did not mention the reaction mechanism, it is believed that the reaction could proceed via the transient formation of (dppe)-Pt(SiMe₂H)(SiMe₂NH₂), corresponding to complex 7.

In accordance with the cleavage of the three-membered-ring structure, the signals in the $^{29}\mathrm{Si}$ and $^{31}\mathrm{P}$ NMR spectra were significantly downfield-shifted compared to those for $\mathbf{1}$. The signals of the incorporated $R_n\mathrm{E-H}$ fragments were reasonably assigned in the $^{1}\mathrm{H}$ NMR spectra. Typically, in complex $\mathbf{2}$, the $^{1}\mathrm{H}$ NMR signals assigned to the SiOH and PH fragments were observed at 0.88 (s) and 6.62 (d, $^{1}J_{\mathrm{PH}}=343.5~\mathrm{Hz}$), respectively.

The molecular structures of **2**, **3**, **5**, and **6** are shown in Figures 1, 2, 3, and 4, respectively. These complexes adopt the normal three-legged piano-stool geometry. Besides the Cp* and CO ligands, the iron center possesses the SiMe₂ER_n (ER_n = OH, OMe, OPh, S^pTol) and PPh₂H ligands formed through the addition of R_nE-H across the silicon-phosphorus bond. The iron-silicon bond is shorter than the typical iron-silicon single bonds in L_nFeSiR₃ (R = alkyl or aryl), but is comparable to those in heteroatom-substituted silyliron complexes. The shortening is due to back-donation from the iron d_π orbital to the σ * orbital of the Si-E bond.

Our previous communications demonstrated that 1 reacted with 4-(dimethylamino)pyridine (DMAP) or

acetone to give the insertion product.^{6b} We have proposed a mechanism involving the attack of the nucleophiles to 1 to give base-stabilized silylene complexes, followed by the nucleophilic attack of the phosphido ligand toward the α -carbon of the coordinated DMAP and acetone. The formation of 2-8 can also be reasonably explained by assuming the generation of the base-

Selected bond lengths (Å) and angles (deg): Fe-P =2.1571(5), Fe-Si = 2.2947(5), Fe-C1 = 1.7263(17), C1-O1 = 1.166(2), O2-C4 = 1.3551(19), Si-O2 = 1.7034(13), P-H1 = 1.30(2), C1-Fe-P = 96.64(6), C1-Fe-Si =82.05(5), P-Fe-Si = 94.053(17).

stabilized silylene complexes (Scheme 2).8 The lone pair of the phosphido ligand then attacks the proton of the coordinated molecule to give the products. An alternative concerted mechanism involving an Si-P-H-E four-membered ring transition state, however, cannot be ruled out.

Reactions of 1 with Secondary and Primary **Phosphines.** Treatment of 1 with PPh₂H led to the formation of 9 in 71% isolated yield (eq 1). In the ¹H NMR spectrum, the signal of the PH fragment was observed at δ 6.67 as a doublet of doublets (${}^{1}J_{PH} = 346.0$ Hz, ${}^4J_{\rm PH}=1.8$ Hz). A doublet of doublets was also observed in the ²⁹Si NMR spectrum at δ 45.6 (${}^{1}J_{PSi}$ = 83.4 Hz, ${}^{2}J_{PSi} = 40.3$ Hz). Furthermore, in the ${}^{31}P\{{}^{1}H\}$ NMR spectrum, two coupled doublets were observed at δ -31.9 and 66.1 with a coupling constant of $J_{PP} = 15.2$ Hz. As the ³¹P NMR signal of Cp*(CO)₂SiMe₂PPh₂

Scheme 2 Plausible Formation Mechanism of 2-8

appears at δ -44.1, 6b these two doublet signals can be assigned to the SiPPh2 and PPh2H fragments, respec-

The formation of 9, in addition to the mechanism shown in Scheme 2, can be explained by considering the validity of an alternative mechanism involving the coordination of PPh₂H to the iron center through cleavage of the iron-phosphorus bond. To clarify the mechanism, 1 was reacted with PPhH2. This reaction also proceeded quickly at room temperature to give 10 as a 1:1 mixture of two diastereomers in 77% isolated yield (eq 2). One of the diastereomers was unequivocally determined by X-ray diffraction analysis (Figure 5). Besides the Cp* and CO ligands, the iron center possesses the SiMe₂P(H)Ph and PPh₂H ligands, clearly indicating that complexes 9 and 10 were formed through 1,2-additon of the phosphorus-hydrogen bonds across the phosphorus-silicon bond. Thus, the alternative mechanism mentioned above can be ruled out.

Conclusion

The reactions of phosphasilametallacyclopropane 1 with water, MeOH, ^tBuOH, PhOH, ^pTolSH, Et₂NH, PhNH₂, Ph₂PH, and PhPH₂ were shown to proceed

^{(8) (}a) Ogino, H. Chem. Rec. 2002, 2, 291. (b) Okazaki, M.; Tobita, H.; Ogino, H. Dalton Trans. 2003, 493.

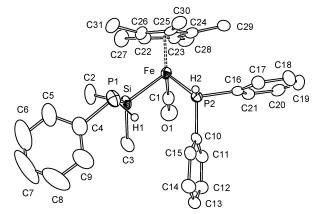

Figure 5. Molecular structure of **10** at the 50% probability level. Selected bond lengths (Å) and angles (deg): Fe-P2 = 2.1673(16), Fe-Si = 2.3212(17), Fe-C1 = 1.737(6), P1-Si = 2.305(2), C1-O1 = 1.158(7), P1-H1 = 1.26(7), P2-H2 = 1.31(5), C1 - Fe - P2 = 96.5(2), C1 - Fe - Si = 82.86(19),P2-Fe-Si = 91.64(6), Fe-Si-P1 = 111.14(8).

immediately at room temperature to give the corresponding 1,2-additon products through cleavage of the silicon-phosphorus bond. Cleavage of the iron-silicon or iron-phosphorus bond was not observed in any of these reactions. To the best of the authors' knowledge, the carbon analogue of 1, phosphametallacyclopropapne, does not exhibit this type of reactivity toward substrates with polarized E-H bonds.9 Thus, the novel reactivity of phosphasilametallacyclopropane is attributable to the highly polarized silicon-phosphorus bond.

Experimental Section

General Procedures. All manipulations were carried out under a dry nitrogen atmosphere. Reagent-grade hexane and pentane were distilled from sodium-benzophenone ketyl immediately prior to use. Benzene- d_6 was dried over a potassium mirror and transferred to an NMR tube under vacuum. Dichloromethane- d_2 was distilled from CaH₂, dried over a molecular sieves (3 Å), and transferred to an NMR tube under vacuum. Methanol was distilled from Mg(OMe)2 and stored in the presence of molecular sieves 3 Å. ^tBuOH was distilled from CaH₂ and stored in the presence of molecular sieves 4 Å. ^pTolSH was purified by recrystallization from pentane. NEt₂H and aniline were distilled from KOH and CaH₂, respectively, prior to use. PPh₂H¹⁰ and PPhH₂¹¹ were prepared according to literature methods. Other chemicals were purchased and used as received. NMR data were recorded on a Bruker ARX-300 or AV-300 spectrometer. $^{29}\mathrm{Si}$ NMR spectra were obtained using the DEPT pulse sequence technique. IR spectra were recorded on a Horiba FT-200 spectrometer. Mass spectral data were obtained using a JEOL JMS-HX110 or Hitachi M2500S spectrometer.

Reaction of 1 with H₂O. A Pyrex tube (20 mm o.d.) equipped with a greaseless vacuum valve and a stirrer bar was charged with 1 (19 mg, 0.041 mmol), pentane (5 mL), and an excess of H₂O (20 µL) in this order under high vacuum by the trap-to-trap transfer technique. The reaction mixture was then stirred at room temperature for 30 min. Subsequent removal of volatiles gave spectroscopically pure 2 as an orange powder. Yield: 16 mg (81%). Anal. X-ray Diffraction Analysis. Single crystals of **2**, **3**, **5**, **6**· $1/2C_5H_{12}$, and **10** were obtained by cooling the solutions at -30 °C. Intensity data were collected on a RIGAKU RAXIS-RAPID imaging plate diffractometer with graphite-monochromated Mo K α radiation at 150 K. The data were corrected for Lorentz and polarization effects, and numerical absorption corrections were applied. The crystallographic data are listed in Table 2.

The structure was solved by Patterson and Fourier transform methods using SHELXS-97¹² and refined by full matrix least-squares techniques on all F^2 data (SHELXL-97).¹³ In each complex, the hydrogen atom on the phosphorus and nitrogen atoms were located by the differential Fourier map and refined isotropically.
