butyricum suspended in paraffin oil into the left hindpaw footpad of male Lewis rats ( $160-180 \mathrm{~g}$ ). Hindpaw volumes were measured by a mercury displacement method. ${ }^{49}$ The inflammation induced in the injected paw on day 3 is designated as the primary lesion. The inflammation of the noninjected paw on day 16 is designated as the secondary lesion. Unless otherwise indicated, test compounds were homogenized in aqueous $0.5 \%$ gum tragacanth and administered po in a volume of $10 \mathrm{~mL} / \mathrm{kg}$ of body weight, on days $0-10$. For the purpose of these studies, antiarthritic activity was measured on the secondary lesion (day 16) in the treated animals relative to the controls (non drug treated). In this model spirogermanium's activity ranged from 50 to $100 \%$ activity (mean of 15 experiments- $68 \%$ ) and in the results section is designated as 1.00 (at $30 \mathrm{mg} / \mathrm{kg}$ ). Statistically significant activity in the biological assays was determined using the Student's $t$ test.

Suppressor Cell Coculture Assay. Spleen cells from azaspirane analogue treated or control animals were established in RPMI with $10 \%$ fetal bovine serum (RPMI-10) at $5 \times 10^{6} / \mathrm{mL}$. Coculture experiments were carried out by first adding varying numbers of the putative suppressor cells ( 0.15 to $5 \times 10^{5}$ ) to wells of 96 -well round-bottomed microtiter plates (Linbro, Flow Laboratories) in $100 \mu \mathrm{~L}$ of RPMI-10. These were then irradiated ( 2000 rad) in a $\gamma$ cell 40 with a Cesium- 137 source. To these cultures were added $5 \times 10^{5}$ normal cells and an optimal concentration of Con A ( $5 \mu \mathrm{~g} / \mathrm{mL}$ ), and the final volume was adjusted to 200 $\mu \mathrm{L}$. Cell cultures were incubated for 72 h at $37^{\circ} \mathrm{C}$ in a $5 \% \mathrm{CO}_{2}$ atmosphere and pulsed with $0.5 \mu \mathrm{Ci}\left[{ }^{3} \mathrm{H}\right]$ thymidine (specific activity $1.9 \mu \mathrm{Ci} / \mathrm{mmol}$; Schwarz/Mann, Orangeburg, NY) for the last 18 h of culture. The cells were harvested on an automated multiple sample harvester and cell-associated radioactivity was counted in a Beckman liquid-scintillation counter. Suppressor cell activity is determined by calculating the percent inhibition of proliferation compared to control cultures. For comparison of azaspirane analogues, a program was developed that could be used to compare suppressor cells generated in different experi-
(49) Wehb, E. F.; Griswold, D. E. J. Pharm. Methods 1984, 12, 149.
ments and the activities of different compounds. This was calculated in the following manner. A plot of percent suppression at different cell concentrations (dependent variable) vs the logarithm (base $e$ ) of the number of suppressor cells (independent variable) was generated and the area under the curve (AUC) represented by the data points of this plot was determined by the trapezoidal rule. The trapezoidal rule provides AUC by means of the summation of the areas of the trapezoids whose vertices are located at adjacent values of the independent variable and the corresponding values of the dependent variable. Spirogermanium (1) at $30 \mathrm{mg} / \mathrm{kg}$ for 11 days, administered po, assayed on day 16 gives an average value of 100 units by this method (mean value derived from three experiments). All unit values for analogues were standardized to the activity of spirogermanium. On the basis of our experience with these compounds we do not consider an AUC of less than 70 for suppressor cells to have meaningful biological activity, whereas values above this correspond to activity in the AA rat (and other autoimmune disease models). In addition, we consider that it requires a change of approximately 70 units in suppressor cell activity (AUC) to result in a meaningful change in the immune profile of treated animals.

Acknowledgment. We wish to thank Dr. Charles Debrosse (SK\&F) for performing high-field ( $360-\mathrm{MHz}$ ) proton magnetic resonance experiments; Dr. Randall Johnson for review of the manuscript; Dr. Frank Brown for helpful discussions; and Glover Campbell, John Hutchman, Diane Olivera, Barbara Swift and Charles Wolff (SK\&F) and Candace Keene (JM) for technical assistance. The program for analyzing suppressor cell activity by measuring the area under the curve (AUC) was designed by Robert Gagnon and Dr. Gary Hensler. We also thank Evelyn Leitham for secretarial assistance.

# Synthesis, Biological Evaluation, and Quantitative Structure-Activity Relationship Analysis of [ $\beta$-(Aroylamino)ethyl]piperazines and -piperidines and [2-[(Arylamino)carbonyl]ethyl]piperazines, -piperidines, -pyrazinopyridoindoles, and -pyrazinoisoquinolines. A New Class of Potent $H_{1}$ Antagonists ${ }^{1}$ 

Mridula Saxena, Shiv K. Agarwal, G. K. Patnaik, and Anil K. Saxena*<br>Central Drug Research Institute, Lucknow 226 001, India. Received January 3, 1990

Some [ $\beta$-(Aroylamino)ethyl]piperazines and -piperidines and [2-[(Arylamino)carbonyl]ethyl]piperazines, -piperidines, -pyrazinopyridoindoles, and -pyrazinoisoquinolines have been synthesized and their H 1 -antagonistic activity studied in isolated guinea pig ileum. Quantitative structure-activity relationship analysis indicates that the hydrophobicity of the side chain of these compounds plays a major role in their activity while steric and electronic factors are of secondary importance. All these compounds act on a common receptor and appear to interact similarly with the receptor.

Earlier work in this laboratory on 2 -substituted $1,2,3,4,6,7,12,12$ a-octahydropyrazino $\left[2^{\prime}, 1^{\prime}: 6,1\right]$ pyrido $[3,4-$ $b$ ]indoles $(1)^{2,3}$ had shown that the presence of a $\beta$-(aroylamino)ethyl side chain at the 2 -position results in potent $\mathrm{H}_{1}$-antagonistic activity. The contributions of the substructure $\left(\mathrm{CH}_{2}\right)_{2} \mathrm{NHCOAr}$ and of hydrophobic interactions

[^0]to the activity were quantified. It was suggested that a hydrophobic substituent at the ortho ( $\pi_{0}$ ) or para ( $\pi_{\mathrm{p}}$ ) positions of 1 contributes more to the activity than a substituent at the meta ( $\pi_{\mathrm{m}}$ ) position and that the activity is enhanced by a bulky substituent at the ortho position of the side-chain phenyl ring. This effect was similar to the effect of a bulky substituent in one of the phenyl rings of diphenhydramine ( $2, R=H$ ) observed by Kutter and Hansch. ${ }^{4}$ Since 1 and 2 produce a similar biological re-

[^1]

Figure 1. Complimentarity between $1\left(\mathrm{R}=-\left(\mathrm{CH}_{2}\right)_{2} \mathrm{NHCOC}_{6} \mathrm{H}_{5}\right)$ (thick line) and 2 (dotted line).

Figure 2. Possible subsites on $\mathrm{H}_{1}$ receptor involved in interactions with $1\left(\mathrm{R}=-\left(\mathrm{CH}_{2}\right)_{2} \mathrm{NHCOAr}\right)$.
sponse, the aromatic rings and the tertiary N in the 2 position of 1 probably occupy the same receptor site as the phenyl rings and tertiary N of 2. This is possible only if the side chain in 1 exists in a folded conformation at the receptor site (Figure 1). Electronic factors do not seem to make any significant contribution to the activity in either case. However, hydrophobicity was of major importance in the case of 1 , but not in 2 . This difference may be due to greater parallelism between hydrophobicity and the steric parameter $E_{\mathrm{s}}$ in the latter case as compared to the former.

Based on the above observations and on structure-activity relationships studies on some semirigid analogs of diphenhydramine, a model of the $\mathrm{H}_{1}$ receptor having at least four subsites A, B, C, and D was visualized (Figure 2); it was proposed that A and D interact with electron-rich hydrophobic groups, that B is responsible for ionic binding, and that C interacts electrostatically with an electron-rich group. ${ }^{5,6}$ These studies also indicated that: (i) antihistaminics of types 1 and 2 act on a common receptor, (ii) ortho substitution in the phenyl ring of the side chain of 1 is likely to have a conformational effect by making the

Scheme I

## Scheme II

phenyl ring noncoplanar, (iii) hydrophobic interactions are e important at the A subsite than electronic and steric .... ractions, (iv) the distance of the subsite B from subsite $A$ is of prime importance for the activity, and (v) high electron density at the C subsite also contributes to the activity.

With a view to explore further the above model of the $\mathrm{H}_{1}$ rece ${ }^{--} \mathrm{r}$, the compounds $7 \mathrm{a}-\mathrm{f}, 8 \mathrm{a}-\mathrm{d}, 10 \mathrm{a}-\mathrm{e}, 11 \mathrm{a}-\mathrm{e}$, 12a-e, i.... 13a-d, which incorporate the above suggested essential structural requirements for $\mathrm{H}_{1}$-antagonistic activity, have been synthesized and their quantitative structure-activity relationship (QSAR) analysis is described in this paper.

## Chemistry

Condensation of benzylpiperazine or benzylpiperidine with chloroacetonitrile yielded the corresponding 1 -(cya-nomethyl)-4-benzylpiperazine ${ }^{7}$ or -piperidine ${ }^{8}$ ( 3 and 4, respectively), which upon $\mathrm{LiAlH}_{4}$ reduction afforded 5 and 6, respectively. ${ }^{7,8}$ Treatment of the latter compounds with the appropriate aroyl chloride in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ gave 1-( $\beta$-aroylamino)ethyl-4-benzylpiperazines and -piperidines (7a-f and 8a-d, respectively) (Scheme I).

Reaction of $\beta$-bromopropionyl chloride with the appropriate arylamines in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ gave the $\beta$ -bromo- $N$-arylpropionamides ( $9 \mathrm{a}-\mathrm{f}$ ) which upon condensation with the appropriate amine yielded the desired 1-[2-[(arylamino) carbonyl]ethyl]-4-benzylpiperazine or piperidine (10a-e and 11a-e, respectively), 2-[2-[(arylamino) carbonyl]ethyl]-1,2,3,4,6,7,12,12a-octahydro-

## Results

Biological Study. The antihistaminic ( $\mathrm{H}_{1}$ ) activities ( $I_{50}$ ) of the compounds are given in Tables I, III-V. These compounds failed to block the AcH response except for 7 e and 7 f , whose $I_{50}$ values were identical with that of histamine. None of the compounds showed significant CNS depressant activity in mice at a dose of $10 \mathrm{mg} / \mathrm{kg}$ ip.
Quantitative Structure-Activity Relationships. Physicochemical parameters of 32 compounds were correlated with their $I_{50}$ values expressed as $\mu \mathrm{mol} / \mathrm{L}$. Hydrophobicity values of these compounds, expressed in terms of the hydrophobic substituent constant ( $\pi$ ) were taken from the literture, ${ }^{14}$ some of the values were ex-

a The value of $R$ corresponds to the type of structure specified by the numerical value in compound number, e.g. in the compd. 1 a and 7 a the structure type is 1 and 7 , respectively. ${ }^{b}$ The values for all the compounds have been calculated from $I_{50}$ in $\mu \mathrm{g} / \mathrm{mL}$ (Table I-V), except for la-e, for which the values have been taken from ref 2 . ${ }^{c}$ The values for all compounds la-f, 7a-f, 8a-d, 11a-e, 12a-e, and 13a-d have been calculated by using eq $20 .{ }^{d}$ Excluded from analysis as these were nonspecific and blocked AcH also, hence calculated and observed log $I_{50}$ values are also not in agreement.
perimentally verified in octanol/water. Electronic and steric effects were expressed in terms of the Hammet constant ( $\sigma$ ) and molar refractivity (MR), respectively, and their values were taken from the literature. ${ }^{14}$

The compounds were grouped into seven different molecular types, A (1a-f), B (7a-f), C (8a-d), D (10a-e), E (11a-e), F (12a-e), and G (13a-d) for QSAR analysis. The data for compounds of group A have been taken from earlier work ${ }^{2}$ in this laboratory. Since hydrophobicity is an important parameter, its effect on the activity was analyzed separately in each group, and the regression equations 1-7 (Table VII) were derived which show a correlation between $\log 1 / I_{50}$ and the hydrophobicity of the side-chain phenyl group. Equations 8-16 describe similar correlations for compounds in certain combinations
of groups, namely, BC, DE, DF, EG, FG, DFG, DEFG, AG, and $B G$, respectively. Equations $17-18$ show the correlations between $\log 1 / I_{50}$ for different types of compounds having a similar set of substituents.

It was evident from our earlier QSAR studies on 2substituted pyrazinopyridoindoles ${ }^{2}$ that the hydrophobicity of the side chain plays an important role, whereas the effects of electronic and steric parameters are secondary. In order to see if the side chain phenyl ring of these prototypes (groups A-G) undergoes similar biomolecular interactions in terms of hydrophobic, electronic, and steric effects, three equations, $19,20,22$, were derived which describe the correlations between $\log 1 / I_{50}$ and the parameters $\pi$, MR, and $\sigma$ taken together for the groups A , $\mathrm{B}-\mathrm{G}$, and $\mathrm{A}-\mathrm{G}$, respectively. In order to check the sta-

tistical justification of the inclusion of additional parameters in eq 15 to obtain eq 22, eq 21 has been derived.

## Discussion

QSAR. Quantitative Structure-Activity Relationships. The QSAR of compounds 1a-f, 7a-f, 8a-d, 10a-e, $11 \mathbf{a}-\mathbf{e}, 12 \mathbf{a}-\mathbf{e}$, and $13 \mathbf{a}-\mathbf{d}$, which incorporate all the essential structural requirements suggested in the proposed model of a $\mathrm{H}_{1}$ receptor antagonist, have been studied. In view of the observation that compounds of type 1 having an ortho substituent in the aryl part of the side chain showed better activity than those with a meta or a para substituent, only ortho-substituted compounds were studied (Tables VI and VII).

It is evident from eqs $2-7$ that in all these compounds hydrophobicity plays a major role similar to that in $\mathbf{1 a - f}$. The slope values given by the equation are almost identical $(0.375 \pm 0.045)$ for different molecular prototypes (groups $\mathrm{A}-\mathrm{G}$ ), which indicates that the change in activity due to the same substructural variation in the side-chain phenyl ring is similar in all prototypes. This would in turn suggest that the side-chain phenyl ring in all these compounds occupy the same receptor site. The low significance $(<97.5 \%)$ of the eqs $2,3,5$, and 6 may be due to the small number of compounds in the set, because statistically significant results were obtained (eqs 8-14) in the case of the combined groups BC, DE, DF, EG, FG, DFG, and DEFG, having a larger number of compounds in the set. All the compounds may be grouped together if the indicator variable IA is used to show the presence of the pyrazinopyridoindole skeleton (presence of IA $=1$, absence of IA $=0$ ). The three-dimensional plot of the data is shown in Figure 3, from which it is clear that the plane bounded by the dotted line correlates well the antihistaminic activity with $\pi$ and IA and eq 15 describing this plane has a highly statistically significant correlation coefficient ( $R=0.92$ ), as shown by the $F$ test $\left[F_{(2,30)}=\right.$ 83.72; $F_{\{2,30 \propto 0.001)}=8.77$ ], with low standard deviation. The regression coefficients were also $100 \%$ significant. The equations describing the interrelationship between the observed activities in the different groups for the same set of substituents are linear, with the regression coefficient values close to 1 (eq 17-18). The differences observed in the order of activity of different groups among $\beta$-(aroyl-
amino) ethyl derivatives $(\mathrm{A}>\mathrm{B}>\mathrm{C})$ and among $\beta$-arylpropionamide derivatives ( $\mathrm{E}>\mathrm{F}>\mathrm{D}$ ) would indicate that either the subsite $C$ (Figure 2) is not essential or its requirement of electrons is being provided by the side chain carbonyl, particularly in the case of 4-benzylpiperidines (group E). The difference in the intercept values given by the eqs 1 and 4 suggests that the orientation of the -NHCO - fragment modulates the activity.

Equation 19, with only three variables and six data points, though not acceptable, was derived only to compare the change in antihistaminic activity with substructural variation in terms of all the three effects, viz. hydrophobic $(\pi)$, steric (MR), and electronic ( $\sigma$ ) in pyrazinopyridoindoles, while the corresponding eq 20 , for all the other compounds, which is acceptable, describes the correlation of the activity with all these parameters. The identical slope values $0.325 \pm 0.021,0.154 \pm 0.01$, and $0.0115 \pm 0.004$ shown by both these equations for $\pi, \sigma$, and $M R$, respectively, indicate that the side-chain phenyl ring in all these molecules occupies the same receptor site and suggest that at subsite $A$ all these molecules experience the same kind of biomolecular interactions. The general equation (22) for all the compounds has been derived by inclusion of the indicator variable IA for the pyrazinopyridoindole skeleton in eq 20 or by stepwise inclusion in eq 15 , of the MR parameter leading to eq 21 , followed by inclusion of the $\sigma$ parameter. The independent parameters used in deriving eq 22 do not intercorrelate, as shown by the correlation matrix (Table VIII). The equation is statistically significant and predicts well the observed activity (Table VI). This equation (22) is a significant improvement over eq 15 as shown by the comparative $F$ test $\left(F_{(2,28)}=9.0\right.$; $\left.F_{(2,28 \propto 0.001)}=8.93\right)$.

In conclusion, these compounds appear to act on a common receptor and the essential structural requirements for the molecule to exhibit $\mathrm{H}_{1}$ antihistaminic activity are the presence of substructures which can interact at the subsites $A, B$, and $D$, while interaction at the subsite $C$ and orientation of the -NHCO - fragment modulate the activity. These studies indicate that the application and predictive value of classical QSAR (physicochemical approach) are not limited to prototypes and that it can be used for the mapping of receptor sites provided the substructures competing for the same receptor sites have been

Figure 3. Three dimensional plot describing correlation of antihistaminic activity $\log 1 / I_{50}$ with hydrophobic $\pi$ and indicator IA parameters.

## identified in different prototypes.

## Experimental Section

All melting points were determined in an electrically heated apparatus (Tempo and Toshniwal) and are uncorrected. The compounds were routinely checked for purity by TLC on silica gel or alumina plates and their structures were verified by their IR spectra measured on Perkin-Elmer 137 or 157 spectrophotometers ( $\gamma$ max in $\mathrm{cm}^{-1}$ ), ${ }^{1} \mathrm{H}$ NMR spectra on a Varian EM-360L (CA) ( 60 MHz ) or a Perkin-Elmer R-32 ( 90 MHz ) spectrometer with TMS as internal reference (chemical shifts in $\delta \mathrm{ppm}$ ), and mass spectra on a JEOL-JMS D-300 spectrometer. Elemental analyses were performed by the microanalysis section of this institute and were within $\pm 0.4 \%$ of the calculated values.

1-(Cyanomethyl)-4-benzylpiperazine (3). Chloroacetonitrile $(8.3 \mathrm{~g}, 0.11 \mathrm{~mol})$ was added dropwise to a stirred mixture of 4-benzylpiperazine ( $17.6 \mathrm{~g}, 0.1 \mathrm{~mol}$ ) and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ( $11.66 \mathrm{~g}, 0.11$ mol) in acetone ( 50 mL ) at $0^{\circ} \mathrm{C}$. The reaction mixture was stirred for 2 h at ambient temperature and then evaporated in vacuo. The solid obtained was triturated with water ( 15 mL ) and extracted with ether ( $2 \times 40 \mathrm{~mL}$ ). The organic layer was washed with water ( $2 \times 10 \mathrm{~mL}$ ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and evaporated to dryness to give 3 as an oil, (lit. bp $152-55^{\circ} \mathrm{C} / 0.2$ $\mathrm{mm})$ yield $20.1 \mathrm{~g}(93.5 \%)$.

1-(Cyanomethyl)-4-benzylpiperidine (4). It was prepared from 4-benzylpiperidine ( $17.5 \mathrm{~g}, 0.1 \mathrm{~mol}$ ) by the procedure described for 3 . The compound 4 was crystallized from ether/ hexane: yield $15 \mathrm{~g}(70 \%)$; mp $65^{\circ} \mathrm{C}$ (lit. ${ }^{8} \mathrm{mp} 68^{\circ} \mathrm{C}$ ).

1-( $\beta$-Aminoethyl)-4-benzylpiperazine (5). A solution of 3 $(10.75 \mathrm{~g}, 0.05 \mathrm{~mol})$ in dry tetrahydrofuran ( 50 mL ) was added dropwise to a stirred suspension of $\mathrm{LiAlH}_{4}(5 \mathrm{~g})$ in dry tetrahydrofuran ( 150 mL ). The reaction mixture was refluxed with stirring for 24 h and cooled. The excess of $\mathrm{LiAlH}_{4}$ was decomposed by addition of water and $10 \%$ aqueous NaOH , and the solution was filtered. The filtrate was evaporated to give 5 as an oil (lit. ${ }^{6}$ bp $180-87^{\circ} \mathrm{C} / 13 \mathrm{~mm}$ ), yield $10 \mathrm{~g}(91 \%)$.

1-( $\beta$-Aminoethyl)-4-benzylpiperidine (6). The reduction of $4(10.7 \mathrm{~g}, 0.05 \mathrm{~mol})$ was carried out with $\mathrm{LiAlH}_{4}(5 \mathrm{~g})$ under similar experimental conditions as described for 5 . The compound 6 was obtained as an oil (lit. ${ }^{7}$ bp $121-130^{\circ} \mathrm{C} / 0.04 \mathrm{~mm}$ ), yield 10.7 g ( $98 \%$ ).

1-( $\beta$-Benzamidoethyl)-4-benzylpiperazine (7f). Benzoyl chloride ( $0.84 \mathrm{~g}, 0.006 \mathrm{~mol}$ ) was added dropwise to a stirred solution of $5(1.095 \mathrm{~g}, 0.005 \mathrm{~mol})$ and $\mathrm{Et}_{3} \mathrm{~N}(1 \mathrm{~mL})$ in dry tetrahydrofuran ( 30 mL ) at $0^{\circ} \mathrm{C}$. The reaction mixture was stirred for 5 h . It was concentrated and diluted with water ( 10 mL ). The resulting mixture was extracted with $\mathrm{CHCl}_{3}(2 \times 20 \mathrm{~mL})$. The combined chloroform extracts were washed first with $10 \%$ aqueous NaOH solution followed by water and then dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The chloroform was removed to give $\mathbf{7 f}$ as an oil which was converted to its hydrochloride by treatment with ethereal

HCl . The $\mathbf{7 f} \mathrm{HCl}$ was crystallized from absolute ethanol/dry ether mixture: yield $0.9 \mathrm{~g}(45 \%) ; \mathrm{mp} 100-102^{\circ} \mathrm{C}$.

Compounds 7a-e were prepared in a similar manner and are described in Table I.

1-( $\beta$-Benzamidoethyl)-4-benzylpiperidine (8d). It was prepared from benzoyl chloride ( $0.84 \mathrm{~g}, 0.006 \mathrm{~mol}$ ) and 6 ( 1.09 $\mathrm{g}, 0.005 \mathrm{~mol}$ ) by a similar method as described for 7 f and crystallized from ethanol: yield $0.9 \mathrm{~g}(45 \%) ; \mathrm{mp} 81^{\circ} \mathrm{C}$.

Compounds 8a-c were prepared in a similar manner (Table I).
$\beta$-Bromo- $\boldsymbol{N}$-phenylpropionamide (9a). $\beta$-Bromopropionyl chloride ( $1.715 \mathrm{~g}, 0.001 \mathrm{~mol}$ ) was added dropwise to a stirred solution of aniline ( $0.93 \mathrm{~g}, 0.001 \mathrm{~mol}$ ) and $\mathrm{Et}_{3} \mathrm{~N}(1 \mathrm{~mL})$ in dry benzene ( 50 mL ) at $5^{\circ} \mathrm{C}$. The reaction mixture was stirred for 4 h . It was concentrated and triturated with water ( 10 mL ). The separated solid was filtered and crystallized from benzene to give 9a: yield $1.7 \mathrm{~g}(75 \%) ; \mathrm{mp} 119-120^{\circ} \mathrm{C}$ (lit. $.^{9} \mathrm{mp} 119-120^{\circ} \mathrm{C}$ ).

Compounds $9 \mathbf{b}-\mathbf{f}$ were made similarly from substituted anilines. The physical data of these compounds are described in Table II.

1-[2-[(Phenylamino) carbonyl]ethyl]-4-benzylpiperazine ( 10 d ). A solution of $9 \mathrm{a}(1.14 \mathrm{~g}, 0.005 \mathrm{~mol})$ in dry DMF ( 25 mL ) was added slowly to a stirred suspension of 4 -benzylpiperazine $(0.88 \mathrm{~g}, 0.005 \mathrm{~mol})$ and dry $\mathrm{Na}_{2} \mathrm{CO}_{3}(0.265 \mathrm{~g}, 0.0025 \mathrm{~mol})$ in dry DMF ( 5 mL ). The reaction mixture was stirred at $70^{\circ} \mathrm{C}$ for 24 h and thereafter water $(15 \mathrm{~mL})$ was added to it. The separated semisolid was extracted into $\mathrm{CHCl}_{3}(3 \times 10 \mathrm{~mL})$. The combined $\mathrm{CHCl}_{3}$ extracts were washed with water ( $2 \times 5 \mathrm{~mL}$ ) and dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Concentration of the extract gave 10 d which was crystallized from methanol: yield $1.32 \mathrm{~g}(81 \%), \mathrm{mp} 94-95$ ${ }^{\circ} \mathrm{C}$.

Compounds 10a-c, 10e, and 11a-e were synthesized similarly (Table III).

2-[2-[(Phenylamino) carbonyl]ethyl]-1,2,3,4,6,7,12,12aoctahydropyrazino $\left[2^{\prime}, 1^{\prime}: 6,1\right]$ pyrido $[3,4-b]$ indole (12a). A solution of $9 \mathrm{~d}(1.28 \mathrm{~g}, 0.0051 \mathrm{~mol})$ in dry DMF ( 20 mL ) was added to a stirred suspension of $1,2,3,4,6,7,12,12 \mathrm{a}$-octahydropyrazino[ $2^{\prime}, 1^{\prime}: 6,1$ ]pyrido $[3,4-b]$ indole ${ }^{12}(1.13 \mathrm{~g}, 0.005 \mathrm{~mol})$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ( $0.265 \mathrm{~g}, 0.0025 \mathrm{~mol}$ ) in dry DMF ( 5 mL ). The reaction mixture was stirred for 36 h at $60^{\circ} \mathrm{C}$ and then cooled and worked up as described for 10 d : yield $1.56 \mathrm{~g}(70 \%), \mathrm{mp} 130-32^{\circ} \mathrm{C}$.

The compounds $\mathbf{1 2 b}$-e were synthesized in a similar manner (Table IV).

2-[2-[(Phenylamino)carbonyl]ethyl]-1,3,4,6,11,11a-hexa-hydro-2H-pyrazino[1,2-b]isoquinoline (13a). Condensation of $1,3,4,6,11,11 a-h e x a h y d r o-2 H$-pyrazino-[1,2-b]isoquinoline ${ }^{13}(0.94$ $\mathrm{g}, 0.005 \mathrm{~mol})$ and $9 f(1.28 \mathrm{~g}, 0.0051 \mathrm{~mol})$ in the presence of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ( $0.265 \mathrm{~g}, 0.0025 \mathrm{~mol}$ ) in DMF ( 5 mL ) under similar conditions as described for 10 d gave 13 a : yield $1.25 \mathrm{~g}(69 \%), \mathrm{mp} 92-93^{\circ} \mathrm{C}$.

Compounds $\mathbf{1 3 b} \mathbf{b}$ d were made similarly (Table V).
Antihistaminic Activity. Antihistaminic activity (H1) was measured on the isolated terminal part of guinea pig ileum ( $5-\mathrm{cm}$ long) suspended in an organ bath containing aerated Tyrode solution ( 20 mL ) at $35^{\circ} \mathrm{C}$ and spasm of the ileum was induced with $3 \times 10^{-8} \mathrm{~g} / \mathrm{mL}$ of histamine. The percentage of inhibition was plotted against different concentrations of the compound and the concentration causing $50 \%$ inhibition ( $I_{50}$ ) was calculated.

Partition Coefficient and QSAR Analysis. The $\log P$ values of compounds 1c, 1e, 12d, 10b, and 10d were measured by using the method described earlier ${ }^{2}$ and found to be $1.80 \pm 0.11,1.52$ $\pm 0.1,1.82 \pm 0.13,3.41 \pm 0.28$, and $2.7 \pm 0.18$, respectively.

The experimental values for $\mathrm{NO}_{2}$ and Cl , namely -0.28 and 0.71 , obtained by subtracting $\log P$ of le from that of 1 c and $\log P$ of 10 b from that of 10 d , respectively, were found to be in agreement with the corresponding values in the literature. ${ }^{14}$ The values for
the other substituents were taken from the literature. ${ }^{14}$ Different equations were generated by using standard multiparameter regression analysis program on Wang/IBM PC XT computers.

Acknowledgment. One of us (M.S.) is thankful to the Director, CDRI for the award of a research fellowship.

ASTA Pharma AG, Weismüllerstrasse 45, D-6000 Frankfurt 1, FRG, and University of Chicago, Chicago, Illinois 60637. Received November 15, 1989

In the course of studies on tranquilizers, new non-benzodiazepine-like compounds were synthesized. These are 1-(3,4,5-trimethoxyphenoxy)-3-[4-(2-methoxyphenyl)piperazinyl]propan-2-ol (INN: enciprazine) and derivatives thereof which were screened pharmacologically in order to evaluate their central nervous system activity. Compounds with marked antiaggressive and anxiolytic properties but without dependence potential could be detected. Enciprazine was selected for clinical investigations.

## Introduction

During recent years the synthesis and biological evaluation of 1 -(alkoxyphenoxy)-3-( $N$-arylpiperaziny)propan2 -ols and related compounds have been under investigation in our laboratories. ${ }^{1}$ In the course of our studies on tranquilizers we tried to synthesize new non-benzo-diazepine-like compounds by combining the $\beta_{2}$-blocker moiety-characteristic of anxiolytics ${ }^{2}$-with phenylpiperazines.
A variety of biological activities of (phenoxyphenylpiperazinyl)propanol derivatives, e.g. local-anaesthetic, hypotensive, and cardiovascular properties, have been reported. ${ }^{3}$ We were especially interested in derivatives acting on the central nervous system (CNS), as the tranquilizing activities of this class of compounds appeared to be very promising. ${ }^{4 \mathrm{a}, \mathrm{b}}$
The great interest in the development of non-benzo-diazepine-like tranquilizers like buspirone ${ }^{4 c}$ led us to study the contribution of substituents in the phenylpiperazine moiety with regard to CNS activities.
This paper deals with the synthesis, the pharmacological screening, and the evaluation of the dependence potential of 1-(3,4,5-trimethoxyphenoxy)-3-(4-phenylpiperazinyl)-propan-2-ols of type I, II, III, and IV (Chart I).

## Chemistry

According to the synthetic sequence for $\beta$-antagonists, condensation of 1-(3,4,5-trimethoxyphenoxy)- 2,3 -epoxypropane with appropriate phenylpiperazines in 2-propanol led to the synthesis of compounds of type I. The corresponding epoxy compound was prepared by reacting commercially available $3,4,5$-trimethoxyphenol (antiarol) with epichlorohydrin in the presence of NaOH . The acylated $o$-hydroxy compounds of type II were obtained by treat-

ment of 1-benzyl-4-(2-hydroxyphenyl)piperazine with acid chlorides in pyridine and subsequent condensation of the hydrogenolytically deprotected $N$-phenylpiperazines as described for compounds of type I.

Compounds of type III were synthesized by reaction of 1-(3,4,5-trimethoxyphenoxy)-3-(4-(2-methoxyphenyl)-piperazinyl]propan-2-ol with the corresponding (hetero)aromatic acid chloride in pyridine.
Starting with 1-benzyl-4-(2-nitrophenyl)piperazine, reduction and debenzylation yielded the corresponding aminophenylpiperazine. After condensation according to the
