Dedicated to the Memory of Steffen Vorwerk

The cellobiose-derived dimer **18**, tetramer **48**, and octamer **49** have been prepared. Acetolytic debenzylation transformed the dimer **15**, obtained from the partially benzylated, dialkynylated cellobiose **2** (*Scheme 1*), into **16** that was deacetylated to **18** (*Scheme 2*), but the analogous debenzylation of the tetramer **14** proved unsatisfactory. We, therefore, avoided benzyl groups and prepared the cellobiose-derived monomer **32** by glycosidation of **27** with the crystalline trichloroacetimidates **30** or **31** (*Scheme 3*). The acceptor **27** was synthesised from 1,6-anhydroglucose in 7 steps (48% overall yield), and the trichloroacetimidates **30** and **31** were obtained in good overall yields from the alkynylated glucopyranoses **29** (*Scheme 3*). The structure of the anomeric trichloroacetimidates **30** and **31** was determined by single crystal X-ray analysis. The alkyne **34**, orthogonally *C*-protected by SiMe<sub>3</sub> and GeMe<sub>3</sub> groups, was transformed by a binomial strategy into the dimer **37**, the tetramer **41**, and the octamer **47** (*Scheme 4*). The unprotected mono- and oligomers **1**, **18**, **48**, and **49** are soluble in H<sub>2</sub>O, MeOH, and DMSO. Their <sup>1</sup>H-NMR specta ((D<sub>6</sub>)DMSO (**1**, **18**, **48**, **49**), CD<sub>3</sub>OD (**1**, **18**, **48**), D<sub>2</sub>O (**49**)) show no signs of association.

**Introduction.** – We plan to assess the influence of H-bonds on the structure and properties of cellulose by comparing cellooligosaccharides with a series of 'acetylenooligosaccharides' obtained from glucose- and cellobiose-glycans, and from higher  $\beta$ -D-1,4-glycans. In these, all or some glycosidic O-atoms are replaced by a butadiynediyl unit [1]. We have prepared a series of glucose-derived oligomers (up to the octamer), where no intramolecular H-bonds between the pyranose residues are possible [2][3]. We have also prepared the cellobiose-derived dialkyne **1** (*Fig. 1*) [4], which still possesses the strong intramolecular C(5)–OH…O–C(5') H-bond typical for cellobiose [5][6].

Analogues of the glucose- and the cellobiose-derived series thus possess either none or one intramolecular H-bond in the monomeric unit, and this difference is expected to

Presented in part at the Royal Society of Chemistry Carbohydrate Group Spring Meeting, Birmingham, 1998, Abstract No. 9.

strongly affect the structure and properties of the analogues. Force-field calculations predict that the 'acetyleno-oligosaccharides' of the glucose-derived series possess a more or less linear, rigid-rod like shape [7]. Analogues of the cellobiose-derived series should possess several conformations of similar energy, depending on the relative orientation of the monomeric units [4] along the butadiynediyl moiety, and resulting in corrugated linear or helical shapes. <sup>1</sup>H-NMR studies of the deprotected oligomers of the glucose-derived series [2] showed no intermolecular association.

We now describe the binomial synthesis of higher oligomers derived from the partially benzylated cellobiose-derived dialkyne **2**, the problems encountered during acetolytic debenzylation of the tetramer **14**, and the synthesis of the mono-, di-, tetra-, and octamers using acetyl, 4-methoxybenzyl, and silyl instead of benzyl (Bn) protecting groups. For the preparation of the monomer, we glycosylated an ethynylated  $\beta$ -*C*-glucopyranoside by crystalline monoethynylated trichloroacetimidates, and report the crystal structure analysis of these trichloroacetimidates. We also report a comparison of physical properties of the deprotected oligomers with those of the glucose-derived analogues.

**Results and Discussion.** – The synthesis of the tetramer 14 started with the protodesilylation and bromodegermylation [3][4] of the orthogonally protected monomer 2 [4], yielding exclusively either the dialkyne 3 or the bromoalkyne 4, respectively (*Scheme 1*). The bromoalkyne 4 was demethoxymethylated to 5 (HCl in THF, 92%) to ensure that the partners (3 and 5) for the *Cadiot-Chodkiewicz*-type cross coupling [8–11] differ sufficiently in polarity to facilitate the separation of the heterocoupled from the homocoupled products<sup>2</sup>). Cross coupling of 3 and 5 under the conditions developed in the glucose-derived series [3][11] gave 67% of the hetero-dimer 6, easily separated by chromatography from the homocoupled 7 (2%) and 8 (2%). Continuing with the orthogonal deprotection/activation strategy, the dimer 6 was, on the one hand, fully desilylated to the mono-*C*-protected alkyne 9 (90%). On the other hand, 6 was acetylated and bromodegermylated to 10 (91%), again resulting in a sufficient difference in polarity of the coupling partners. Cross coupling of 9 and 10 as above yielded 60% of the tetramer 11 together with the homocoupled 12 (2%) and 13 (3%) (*Scheme 1*)<sup>3</sup>.

Acetolytic debenzylation is compatible with one glycosidic bond [15]; to check its compatibility with several glycosidic bonds, we examined the deprotection of the dimer **6** and of the tetramer **14** (*Scheme 2*). The dimer **6** was deprotected in three steps. Treatment with 1N aqueous HCl in MeOH at 40° removed both the methoxymethyl-(MOM) and the Me<sub>3</sub>Ge groups to give 76% of the hexol **15**. Above 60°, one of the glycosidic bonds was selectively hydrolysed, as evidenced by the isolation of **17** after

<sup>&</sup>lt;sup>2</sup>) For a successful application of this strategy in the synthesis of cyclodextrin analogues, see [12-14].

<sup>&</sup>lt;sup>3</sup>) Yields of the cross coupling are 20-25% below those for the benzylated glucose-derived oligomers, carrying C-DOPS and C-GeMe<sub>3</sub> groups [3]. TLC showed no evidence for the decomposition of 1 within 48 h under conditions of the cross coupling, but only 80-85% were recovered after chromatography. Besides the coupling products, polar fractions were obtained by silica-gel chromatography, consisting (<sup>1</sup>H-NMR spectroscopy) of a mixture of unidentified, carbohydrate-derived compounds. The reasons for the different behaviour of glucose- and cellobiose-derived analogues have been analysed by *T. Bohner* (manuscript in preparation), and are related to the nature of the protecting groups.

 $Ac = MeC(O), Bn = PhCH_2, MOM = MeOCH_2$ 

a)  $K_2CO_3$  in MeOH; 90% [4]. b) CuBr, NBS, acetone, 93% [4]. c) 1N HCl, THF; 92%. d)  $[Pd_2(dba)_3]/CuI$ (dba = dibenzylideneacetone), 1,2,2,6,6-pentamethylpiperidine, DMSO; 6 (67%), 7 (2%), 8 (2%). e)  $K_2CO_3$ in MeOH/THF; 90%. f) 1. Ac<sub>2</sub>O, pyridine; 2. NBS, CuBr, acetone; 91%. g) As d); 11 (60%), 12 (2%), 13 (3%). h) 1N HCl, THF; 74%.

SiMe<sub>3</sub>

acetylation of the crude. Acetolytic debenzylation of **15** proceeded best with Me<sub>3</sub>SiOTf (10 mol-%) in Ac<sub>2</sub>O yielding only 51% of the dodecaacetate **16**<sup>4</sup>). The fully deprotected dimer **18** was obtained in nearly quantitative yield by deacetylation of **16** (NaOMe in MeOH). This compound is readily soluble in H<sub>2</sub>O, MeOH, and pyridine, but could not be crystallized.

a) 1n HCl, THF; 76%. b) Ac<sub>2</sub>O, Me<sub>3</sub>SiOTf; 51%. c) NaOMe, MeOH, Amberlite IR-120 (H<sup>+</sup>); 95%.

All attempts to fully deprotect tetramer **11** failed. Acid-mediated protodegermylation and demethoxymethylation yielded 74% of **14** (*Scheme 1*), but the subsequent acetolysis using *Lewis* acids (such as Me<sub>3</sub>SiOTf, BF<sub>3</sub>·OEt<sub>2</sub>, FeCl<sub>3</sub> [16], or ZnI<sub>2</sub>) in Ac<sub>2</sub>O at various temperatures and concentrations gave mixtures of partially debenzylated products together with unidentified polar material. Thus, we had to avoid Bn groups.

Cellobiose-derived dialkynes are most efficiently prepared by glycosidation of monoethynylated glycosyl acceptors with monoethynylated donors [4]. We required a synthesis of a glycosyl acceptor, and donor, devoid of BnO groups.

The glycosyl acceptor **27** was prepared from 1,6-anhydroglucose (**19**) (*Scheme 3*). Triethylsilylation [17] led to the 2,4-di-*O*-silyl ether **20** in 90% yield, besides 7% of the trisilyl ether **21**. Retentive ethynylating opening of the 1,3-dioxolane ring of **20** with lithium (trimethylsilyl)acetylide and freshly sublimed AlCl<sub>3</sub> in the presence of 1 equiv. of 2,4,6-trimethylpyridine gave the *C*-glucopyranoside **22**, which was purified by distillation and isolated in 68%. This modification of *Alzeer*'s method [1] constitutes the shortest and highest yielding way to ethynylated  $\beta$ -*C*-glucopyranosides<sup>5</sup>). The tetrol **23** was obtained in a nearly quantitative yield by acid-catalyzed desilylation.

<sup>&</sup>lt;sup>4</sup>) Only *ca*. 80% of the calculated mass balance of **16** was obtained after chromatography, including elution with MeOH. <sup>1</sup>H-NMR Data for the polar fractions evidence acetylated carbohydrate and aromatic residues.

<sup>&</sup>lt;sup>5</sup>) Exploratory experiments indicate that any  $\beta$ -*C*-glucopyranosides are also available by this procedure.

a) Et<sub>3</sub>SiCl, 1*H*-imidazole, DMF; 20 (90%), 21 (7%). b) BuLi, HC≡CSiMe<sub>3</sub>, AlCl<sub>3</sub>, 2,4,6-trimethylpyridine, toluene; 68%. c) 0.1N HCl, THF/MeOH; 95%. d) 4-Methoxybenzaldehyde dimethyl acetal, TsOH · H<sub>2</sub>O, DMF; 93%. e) 4-Methoxybenzyl trichloroacetimidate, TfOH, Et<sub>2</sub>O; 82%. f) 80% AcOH; 99%. g) TDSCl, 1*H*-imidazole, DMF; 95%. h) H<sub>2</sub>NNH<sub>2</sub> · HOAc, DMF; 93%. i) K<sub>2</sub>CO<sub>3</sub>, Cl<sub>3</sub>CCN, CH<sub>2</sub>Cl<sub>2</sub>; 48 h; 85%. j) K<sub>2</sub>CO<sub>3</sub>, Cl<sub>3</sub>CCN, CH<sub>2</sub>Cl<sub>2</sub>, 1.5 h; 70%. k) Me<sub>3</sub>SiOTf, 4-Å mol. sieves, CH<sub>2</sub>Cl<sub>2</sub>; 90%. l) DIBAH, THF; 99%. m) 1. (Me<sub>3</sub>Si)<sub>2</sub>NH, Me<sub>3</sub>SiCl, CH<sub>2</sub>Cl<sub>2</sub>; 2. LDA, Me<sub>3</sub>GeCl, AcOH/THF/H<sub>2</sub>O 1:1:1; 90%.

Transacetalization of **23** with anisaldehyde dimethyl acetal [18] yielded 93% of the crystalline **24** that was 4-methoxybenzylated (4-methoxybenzyl trichloroacetimidate, cat. TfOH [19]) to **25**. Hydrolysis of **25** (80% aq. AcOH [20]) gave **26** that was selectively *O*-silylated with (thexyl)(dimethyl)silyl chloride (= chlorodimethyl(1,1,2-trimethylpropyl)silane; TDSCl) [21]. This sequence yielded 84% of the glycosyl acceptor **27** from **24**.

The structure of **23** was established by X-ray analysis<sup>6</sup>) (*Fig.* 2). The intensities for **23** were recorded at 293 K (R = 0.0442). The pyranose ring adopts a  ${}^{4}C_{1}$ -conformation, as shown by the endocyclic torsion angles (*Table 1*). The *gg*-conformation of the CH<sub>2</sub>OH group is characterized by the endocyclic torsion angles  $\chi^{1}(O(7)-C(7)-C(7))$ 

<sup>&</sup>lt;sup>6</sup>) Coordinates and thermal parameters were deposited with the *Cambridge Crystallographic Data Center*, 12, Union Road, Cambridge CB2 1 EZ, UK.

 $C(8)-O(8)) = -67.3(3)^{\circ}$  and  $\chi^2(C(6)-C(7)-C(8)-O(8)) = 53.0(4)^{\circ}$ . The ethynyl substituent is nearly linear (C(1)-C(2)-C(3) bond angle = 177.0(4)^{\circ}). All bond lengths are within standard values. Intermolecular H-bonds are found between  $O(6) \cdots O(5')$  (2.725(4) Å;  $2-x, -0.5+y, 1-z; O(6)-H\cdots O(5') = 1.84$  Å),  $O(5')\cdots O(8'')$  (2.784(4) Å;  $1+x,y,z; O(5')-H\cdots O(8'') = 2.11$  Å), and  $O(8'')\cdots O(6')$  (2.747(4) Å;  $-1+x,y,z; O(8'')-H\cdots O(6') = 1.79$  Å) forming a two-dimensional network in the *a,b* plane and an infinite chain running along the *b* axis (*Fig. 2*). Thus, the cystal structure of **23** belongs to *Class I* according to the classification of H-bonding patterns in monosaccharides by *Jeffrey* and *Saenger* [22].

 $\rightarrow \cdots O6-H \cdots O5'-H \cdots O8''-H \cdots O6'-H \cdots \rightarrow 1.79$

Several Ac-protected ethynylated glucopyranosyl donors were examined for the glycosidation of **27**<sup>7</sup>). The best results were obtained with the glucopyranosyl trichloroacetimidates **30** and **31**. They were prepared from the known ethynylated acetate **28** [4] by selective deacetylation with hydrazinium acetate to **29** (93%,  $\alpha$ -D/ $\beta$ -D 63 :37) followed by base-catalyzed addition of Cl<sub>3</sub>CCN under either thermodynamic or kinetic control, following *Schmidt*'s procedures [23]. Thus, treatment with Cl<sub>3</sub>CCN in the presence of K<sub>2</sub>CO<sub>3</sub> in CH<sub>2</sub>Cl<sub>2</sub> for 48 h gave 85% of **30/31** (88 :12), while the ratio **30/31** was 17:83 after a similar treatment for 1 h. The pure anomers **30** and **31** were obtained by recrystallization. Glycosidation of the acceptor **27** with either **30** or **31** in the presence of Me<sub>3</sub>SiOTf in CH<sub>2</sub>Cl<sub>2</sub> at  $-10^{\circ}$  led to the dialkyne **32** in 85–90% yield on a multigram scale. Deacetylation of **32** with diisobutylaluminium hydride (DIBAH) in THF [4] yielded 99% of **33**, and subsequent trimethylgermylation provided 90% of the orthogonally protected dialkyne **34** (*Scheme 3*).

Glycosyl trichloroacetimidates are presumably the most widely used class of glycosyl donors [24], but so far no solid-state structure of these compounds has been published. The structure of the pair of anomeric imidates 30 and 31 was determined by X-ray analysis<sup>6</sup>) (*Fig. 3*). The intensities for **30** were recorded at 293 K and for **31** at 203 K. Both structures show heavy disorder, which could not be resolved adequately, especially for 30 (see *Exper. Part*); the final R values are 0.092 (30) and 0.0573 (31). respectively. The discussion of bond lengths and angles can, therefore, only point to trends. Both imidates adopt the  ${}^{4}C_{1}$  conformation, as shown by the endocyclic torsion angles (*Table 2*). The trichloroacetimidoyl group of the  $\alpha$ -D-anomer **30** is nearly anticlinal to the C(1) - O(5) bond  $(\Psi(O)(5) - C(1) - O(1) - C(9)) = 119.1(9)^{\circ}$ , whereas, in the  $\beta$ -D-anomer **31**, the torsion angle  $\Psi$  is  $-83.4(4)^{\circ}$ . In both anomers, the imino group is syn-periplanar to the C(1)-O(1) bond  $(\Theta(C(1)-O(1)-C(9)=N(9)) =$  $-1(2)^{\circ}$  for **30** and  $\Theta = 4.0(7)^{\circ}$  for **31**). Schmidt et al. [25] have calculated the conformation of the imino group of an  $\alpha$ -D-pyranosyl trichloroacetimidate in the gas phase, and found  $\Psi = 70 \pm 1^{\circ}$  (MM2) or  $\Psi = 81.3^{\circ}$  (MNDO) and  $\Theta = 9 \pm 1^{\circ}$  (MM2) or  $\Theta = 19.8^{\circ}$  (MNDO), *i.e.*, significantly differing from the solid-state values of **30** and **31**. The gg-conformation of the AcOCH<sub>2</sub> group in 30 is characterized by the endocyclic torsion angles  $\chi^1(O(5)-C(5)-C(6)-O(6)) = -68.2(11)^\circ$  and  $\chi^2(C(4)-C(5)-C(6)-C(6)-C(6)) = -68.2(11)^\circ$ O(6) = 54.5(13)°, while the endocyclic torsion angles  $\chi^1 = 64.7(4)^\circ$  and  $\chi^2 =$  $-176.1(3)^{\circ}$  characterize the gt-conformation of the AcOCH<sub>2</sub> group in **31**. The ethynyl substituent is nearly linear in both anomers; the bond angles C(4) - C(7) - C(8) being  $178.5(13)^{\circ}$  (**30**) and  $178.4(5)^{\circ}$  (**31**), respectively.

An anomeric effect in the  $\alpha$ -D-anomer **30** is indicated by the shortening of the C(1)-O(5) (1.368(13) Å<sup>8</sup>)) and lengthening of the C(1)-O(1) (1.448(13) Å) bond (*Table 2*). Although the conformation of the imidate moiety in the  $\beta$ -D-anomer is close to the one required for an *exo*-anomeric effect [26], the length of both C(1)-O bonds (1.423(5) and 1.413(5) Å) is in the normal range (*Table 2*). This is rationalized by the strong n(O(1))  $\rightarrow \pi^*(C(9)=N)$  interaction, as supported by the short O(1)-C(9) bond (1.330(5) Å).

<sup>&</sup>lt;sup>7</sup>) Thiophenyl glycoside, phenyltetrazolyl glycoside, glycosyl fluoride, and glycosyl bromide [21].

<sup>8)</sup> The shortening is largely an effect of the disorder of the crystal structure.

Fig. 3. X-Ray crystal-structure analysis of **30** and **31**: ORTEP [36] presentation (ellipsoids enclose 25% for **30** and 50% for **31** of the electron density) and unit cell (PLUTO [37]). Only one position of the disordered atoms is shown, arrows indicating the close contacts discussed in the text.

Only approximate intermolecular distances could be obtained for **30** because of the disordered Cl-atoms and C(3)-O/C(6)-O acyl groups. The N-atom of **30** is located 3.14(1) Å away from the neighbouring O(5) (*cf. Fig. 3*), a value close to the *van der*

Table 2. Selected Torsion Angles [°] and Bond Lengths [Å] in **30** and **31**. Standard deviations in parentheses. Numbering according to Fig. 3.

*Waals* distance indicating a weak intermolecular H-bond  $(N-H \cdots O(5) = 2.38 \text{ Å})$ ; in the  $\beta$ -D-anomer **31** the distance of 3.10(1) Å between the N-atom and the ring O-atom indicates a intramolecular interaction  $(N-H \cdots O(5) = 2.58 \text{ Å}, \text{ (}N-H \cdots O) = 116(3)^{\circ})$ . Both anomers show an intermolecular  $C_{sp}-H \cdots O$  H-bond [27][28], characterized by the distance between C(8) of the  $\alpha$ -D-anomer **30** and the C(2)–OAc carbonyl O-atom of 3.24(2) Å. The shortest intermolecular contact in the  $\beta$ -D-anomer **31** (3.19(1) Å) is between C(8) and the C(6)–OAc carbonyl O-atom (*Fig. 3*). Similar short  $C_{sp}-H \cdots O$  contacts have been observed, *e.g.*, in the crystal structures of *N*-methylpropiolamide (CSD MPROLA [29]) and (*o*-chlorobenzoyl)acetylene (CSD BYACCO [30]). Further evidence for an intermolecular  $C_{sp}-H \cdots O$  H-bond derives from the solid-state (3% KBr) IR spectra of **30** and **31**. The wavenumbers for the  $\tilde{\nu}(\equiv C-H)$  stretching are significantly lower for **30** (3242 cm<sup>-1</sup>) and **31** (3245 cm<sup>-1</sup>) than for the tetraacetate **28** (3272 cm<sup>-1</sup>). In solution (2% in CCl<sub>4</sub>), **30**, **31**, and **28** show an IR  $\tilde{\nu}(\equiv C-H)$  absorption at 3111 cm<sup>-1</sup>.

The new cellobiose-derived dialkyne **34** was transformed along similar lines as described for **2**. Protodesilylation of **34** ( $K_2CO_3/MeOH$ ) yielded 91% of the dialkyne **35**, and acetylation followed by CuBr catalyzed bromodegermylation yielded 90% of the bromoalkyne **36** (*Scheme 4*).

Cross coupling of **35** and **36** in DMSO under the conditions of *Schreiber* and coworkers [31] and *Cai* and *Vasella* [11] led to the dimer **37** (66%). *Ca.* 2% of the trimer **38** was also isolated if the reaction was conducted for 27 h. A control experiment where the bromoalkyne **36** and the dimer **37** were cross-coupled under the same conditions showed a very slow transformation into the trimer **38** (marginal amounts were detectable on TLC after 48 h), possibly due to a CuI-catalyzed degermylation.

Treatment of the dimer **37** with  $K_2CO_3$  in MeOH removed the Me<sub>3</sub>Si and the Ac groups, and yielded 78% of the alkyne **39**, while treatment with *N*-bromosuccinimide (NBS) and CuBr transformed **37** into the bromoalkyne **40** without affecting the other

*a*) K<sub>2</sub>CO<sub>3</sub>, MeOH/THF; 91%. *b*) 1. Ac<sub>2</sub>O, pyridine; 2. NBS, CuBr, acetone; 90%. *c*) [Pd<sub>2</sub>(dba)<sub>3</sub>]/CuI, P(furyl)<sub>3</sub>, Et<sub>3</sub>N, DMSO; 65%. *d*) As *a*); 78%. *e*) NBS, CuBr, acetone; 81%. *f*) Pd<sub>2</sub>(dba)<sub>3</sub>/CuI, P(furyl)<sub>3</sub>, Et<sub>3</sub>N, DMSO; 54%. *g*) K<sub>2</sub>CO<sub>3</sub>, MeOH/THF; 55%. *h*) Et<sub>3</sub>SiCl, 1*H*-imidazole, DMF; 92%. *i*) As *e*); 86%. *j*) 1. protecting groups. Cross coupling of **39** and **40**, similarly as before, gave the tetramer **41** in 54% yield.

Treatment of the tetramer **41** with  $K_2CO_3$  in MeOH/THF gave only 55% of the completely deacetylated and *C*-desilylated alkyne **42** together with 2% of the degermylated alkyne **43** and 7% of the partially deacetylated alkyne **44**. Obviously, the concomitant deacetylation and *C*-desilylation of the tetramer was no longer selective, marking the limits of the scope of these conditions for the regioselective deprotection of the prop-2-ynyl ether moiety. To increase the polarity difference between the coupling partners, the tetramer **41** was first triethylsilylated to **45** (92%) and then bromodegermylated to **46** (86%). Cross coupling of **42** and **46** required twice as much of catalyst and phosphine ligand as for the preceding couplings and gave a mixture containing the desired product which could not be separated by column chromatography. The crude mixture was, therefore, acetylated, *O*-desilylated with HF in pyridine, and separated by chromatography, providing 39% of the octamer **47**.

Similarly as observed for the sequential binomial cycles starting with **2**, yields decreased in each cycle and were significantly lower than those realized for the glucose-derived dialkynes [3].

Deprotection of the tetramer **41** (*Scheme 5*) required the oxidative cleavage of the (4-methoxybenzyl)oxy groups with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (= 4,5-dichloro-3,6-dioxocyclohexa-1,4-diene-1,2-dicarbonitrile; DDQ) [32], O-de-silylation with HF in pyridine, and deacetylation to give the deprotected tetramer **48** in 42% overall yield. The deprotected octamer **49** was obtained (34%) from **47** by treatment with DDQ and deacetylation.

a) 1. DDQ, CH<sub>2</sub>Cl<sub>2</sub>/H<sub>2</sub>O 9:1; 2. HF · pyridine, THF, pyridine; NaOMe, MeOH, *Amberlite IR-120* (H<sup>+</sup>); 42%. b) 1. DDQ, CH<sub>2</sub>Cl<sub>2</sub>/H<sub>2</sub>O 9:1; 2. NaOMe, MeOH, *Amberlite IR-120* (H<sup>+</sup>); 34%.

The deprotected dimer **18**, tetramer **48**, and octamer **49** are soluble in H<sub>2</sub>O, MeOH, and DMSO, whereas, in the glucose-derived series, only the dimer was soluble in H<sub>2</sub>O and MeOH, the tetramer and the octamer dissolving only in DMSO. The strong intramolecular  $C(5')-C\cdots$ HO-C(5) H-bonds within each cellobiose unit were evidenced for the dimer **18** by the temperature dependence of the chemical shift of the OH resonances (D<sub>6</sub>)DMSO,  $C(5')-O\cdots$ HO-C(5) ( $\Delta \delta / \Delta T = -1.65$  ppb·K<sup>-1</sup>) and  $C(5''')-O\cdots$ HO-C(7'') ( $\Delta \delta / \Delta T = -1.73$  ppb·K<sup>-1</sup>), but the relative orientation of the monomeric units around the butydiynediyl bridge could not be deduced. The <sup>1</sup>H-NMR spectra of the oligomers are almost superimposable; the signals of the cellobiose units attached to a butadiynediyl unit appearing at slightly lower field ( $\Delta \delta \approx 0.05-0.1$  ppm) than those of the ethynylated residues. Qualitatively, the same behaviour has also been observed for the glucose-derived series. A comparison of selected <sup>1</sup>H-NMR data in CD<sub>3</sub>OD, (D<sub>6</sub>)DMSO, and D<sub>2</sub>O of the deprotected cellobiose-derived oligomers (*Table 3*) shows no evidence for association of these compounds, in agreement with the observations in the glucose-derived series [2].

Table 3. Selected <sup>1</sup>H-NMR Data (23°) of the Deprotected Oligomers. Concentration in parentheses.

The  $\delta(^{13}\text{C})$  values of the propargylic and homopropargylic ethynyl groups of **1**–**6**, **9–11**, **15–18**, **32–42**, **44–46**, **48**, and **49** are given in *Table 4*. The assignments of the *s*'s of  $C \equiv CSiMe_3$  and  $C \equiv CGeMe_3$  are in agreement to the values of the analogous glucose-derived oligomers [2][3]. The *s*'s of the brominated ethynyl groups appear at significantly higher fields, *i.e.*, at 42.20–44.27 ppm for Br $C \equiv C$  and at 75.92–77.97 ppm for Br $C \equiv C$ . The unprotected ethynyl groups show a *d* at 80.04–82.32 and a *s* at 73.65–77.97 ppm. The *d*'s for C(3) and C(4<sup> $\omega$ </sup>) resonate at 69.12–72.26 and 35.72–40.08 ppm, respectively.

We thank the *Swiss National Science Foundation* and *F. Hoffmann-La Roche AG*, Basel, for generous support, and Dr. *B. Bernet* for checking the experimental part.

#### **Experimental Part**

General. Solvents were distilled before use: THF and toluene from Na-benzophenone ketyl, CH<sub>2</sub>Cl<sub>2</sub>, MeCN, and MeOH from CaH<sub>2</sub> and acetone from CaSO<sub>4</sub>. Cl<sub>3</sub>CCN was distilled under Ar prior to use. K<sub>2</sub>CO<sub>3</sub> was heated until glowing. HCl in aq. MeOH was prepared by mixing 83 ml of HCl (37%) with 917 ml of MeOH. Reactions were run under Ar or N<sub>2</sub>. BuLi was titrated [33] before use. AlCl<sub>3</sub> was freshly sublimed and weighted in a glove-box under N<sub>2</sub>. Workup: The mixture was diluted with the indicated solvent and H<sub>2</sub>O, the layers were separated, and the aq. layer was extracted several times with the indicated solvent. The combined org. layers were washed once with brine, dried (MgSO<sub>4</sub>), filtered, and the solvent was removed at 40° under reduced pressure. Qual. TLC: precoated silica-gel plates (*Merck* silica gel 60  $F_{254}$ ), detection by spraying with 5% H<sub>2</sub>SO<sub>4</sub> in EtOH followed by heating to *ca.* 200°. Flash chromatography (FC): silica gel *Merck* 60 (0.04–0.063 mm). M.p's: uncorrected. Optical rotations: 1-dm cell at 20 or 25° and 589 nm. FT-IR: 1–2% soln. in the indicated solvent. <sup>1</sup>H- and <sup>13</sup>C-NMR: at 200, 300, 400 or 500 MHz; 50, 75, 100, or 125 MHz, resp. MS: Chemical ionization (CI) with NH<sub>3</sub>, fast atom bombardment (FAB), or MALDI-TOF. NOBA: 3-Nitrobenzyl alcohol.

4-C-(*Bromoethynyl*)-4-deoxy-β-D-glucopyranosyl-( $1 \rightarrow 6$ )-3,7-anhydro-4,5,8-tri-O-benzyl-1,2-dideoxy-1-C-(*trimethylsilyl*)-D-glycero-D-gulo-oct-1-ynitol (**5**). A soln. of **4** [4] (1.5 g, 1.64 mmol) in THF (16 ml) was treated at r.t. with 1M aq. HCl in MeOH (10 ml), heated for 36 h at 40°, neutralized with Amberlite IRA-900 (OH<sup>-</sup>

Anal. calc. for C<sub>16</sub>H<sub>18</sub>Cl<sub>3</sub>NO<sub>8</sub> (458.68): C 41.90, H 3.96, N 3.05; found: C 41.70, H 4.14, N 2.97.

*X-Ray Analysis of* **30**. Crystals were obtained by isothermic distillation of heptane into a *ca*. 10% soln. of **30** in AcOEt.  $C_{16}H_{18}Cl_3NO_8$  (458.68). Orthorhombic,  $P2_12_12_1$ , a = 9.433(3) Å, b = 10.516(3) Å, c = 22.293(13) Å, V = 2211(2) Å<sup>3</sup>, Z = 4,  $D_{calc.} = 1.378$  Mg/m<sup>3</sup>. The intensities were recorded on a *Enraf-Nonius-CAD-4* diffractometer (graphite monochromator,  $MoK_a$ ,  $\lambda = 0.71073$  Å) at 293(2) K. Of the 2289 total collected reflections, 2234 were independent. The structure was solved with direct methods (SHELXS96 [38]). The non-H-atoms were refined anisotropically with SHELXL92 [35]. The H-atoms were calculated at idealised positions and included in the structure factor calculation with fixed isotropic displacement parameters. Two of the three

Cl-atoms and the 3-O- and 6-O-acyl groups were refined over two positions. The structure converged at an R value of 0.0916 using 1578 reflections with  $I > 3\sigma(I)$ .

2,3,6-Tri-O-acetyl-4-deoxy-4-C-ethynyl-B-D-glucopyranosyl Trichloroacetimidate (31). A soln. of 29 (586.2 mg, 1.87 mmol) and Cl<sub>3</sub>CCN (1.87 ml, 18.65 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (20 ml), was treated in one batch with K<sub>2</sub>CO<sub>3</sub> (327 mg), stirred at r.t. for 90 min, filtered through Celite, concentrated to ca. 8 ml and directly chromatographed ( $\emptyset$  1 cm, 8 g of Si-60, hexane/AcOEt/Et<sub>3</sub>N 2:1:0.1). The product-containing fractions were concentrated to ca. 7 ml and stored for 4 h at  $-20^\circ$ . Filtration gave **31/30** ca. 83: 17 (470 mg, 55%) as colourless needles. Evaporation of the mother liquor gave additional 31/30 ca. 2:1 (128 mg 15%) as a white solid (total 598 mg, 70%). Pure **31** was obtained after recrystallization from heptane/ether,  $R_{\ell}$  (hexane/AcOEt 1:1) 0.61. M.p.  $174 - 175^{\circ}$ .  $[a]_{25}^{25} = -6.9$  (c = 1, CHCl<sub>3</sub>). Anal. calc. for C<sub>16</sub>H<sub>18</sub>Cl<sub>3</sub>NO<sub>8</sub> (458.68): C 41.90, H 3.96, N 3.05; found: C 41.87, H 3.81, N 3.08.

*X-Ray Analysis of* **31**. Crystals were obtained by isothermic distillation of pentane into a *ca*. 10% soln. of **31** in *t*-BuOMe.  $C_{16}H_{18}Cl_3NO_8$  (458.68). Monoclinic,  $P2_1$ , a = 5.581(2) Å, b = 8.891(3) Å, c = 20.951(4) Å,  $\beta = 94.39(3)^\circ$ , V = 1036.5(6) Å<sup>3</sup>, Z = 2,  $D_{calc.} = 1.470$  Mg/m<sup>3</sup>. The crystals were measured on an *Enraf-Nonius-CAD-4* diffractometer (graphite monochromator,  $CuK_a$ ,  $\lambda = 1.54184$  Å) at 203(2) K. Of the 2178 total collected reflections, 1983 were independent. An empirical absorption correction was done by PSI scans of selected reflections. Part of the structure was solved with direct methods, the remaining non-H-atoms were found from a difference *Fourier* map with SHELXS96 [38]. The non-H-atoms were refined anisotropically with SHELXL97 [39]. The H-atoms were refined isotropically except the H-atoms of the Me and alkyne groups, which were calculated at idealized positions and included in the structure-factor calculation with fixed isotropic displacement parameters. The disordered Cl-atoms were refined over two positions. The structure converged at an *R* value of 0.0573 using 1867 reflections with  $I > 3\sigma(I)$ .

2,3,6-Tri-O-acetyl-4-deoxy-4-C-ethynyl- $\beta$ -D-glucopyranosyl-(1  $\rightarrow$  6)-3,7-anhydro-1,2-dideoxy-4,5-bis-O-(4-dox)-4,5-bis methoxybenzyl)-8-O-(thexyldimethylsilyl)-1-C-(trimethylsilyl)-D-glycero-D-gulo-oct-1-ynitol (32). A soln. of 27 (6.69 g, 10.39 mmol) and **30** (5.23 g, 11.42 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (100 ml) was treated with powdered 4-Å molecular sieves (4 g) and stirred at r.t. for 30 min. The mixture was cooled to  $-10^{\circ}$ , treated dropwise with 1.41m Me<sub>3</sub>SiOTf in CH<sub>2</sub>Cl<sub>2</sub> (0.18 ml, 2.5 mol-%), stirred for 5 min, poured into ice-cold sat. NaHCO<sub>3</sub> soln. (10 ml), filtered through *Celite*, and worked up (CH<sub>2</sub>Cl<sub>2</sub>). FC (hexane/AcOEt 5:1 $\rightarrow$ 7:2) gave **32** (8.8 g, 90%). Colourless oil.  $R_{\rm f}$  (hexane/AcOEt 2:1) 0.53.  $[a]_{25}^{25} = -11.15$  (c = 2, CHCl<sub>3</sub>).
