An efficient method is proposed for obtaining tetrahydrobenzo[a]xanthene-11-ones and tetrahydro-[1,3]dioxolo[4,5-b]xanthen-9-ones. The method is based on the use of p-sulfonic acid calix[n] arenes as 10 catalysts under solvent-free condition. The antiproliferative activity of fitity-nine xanthenones against six human cancer cells was studied. The capacity of all compounds to inhibit cancer cells growth was dependent on the histological origin of cells. QSAR studies indicate that among compounds derived from β-naphtol the most efficient compounds against glioma (U251) and renal (NCI-H460) cancer cells are those having higher hydrogen bonding donor ability.

Introduction

Cancer is an important public health concern and a leading cause of death. It accounted for eight million deaths worldwide (ca. 15% of all deaths) in 2010 (38% more than in 1990). 1,2 Many of 20 current chemotherapy drugs have low specificity for tumor cancer cells, and are also toxic to normal cells. Related to the inefficiency of existing drugs against different types of cancer issues, as well as the increasing emergence of strains resistant to these drugs are also reported.3 Indeed, one of the biggest 25 challenges of combating cancer is the development of new anticancer agents that are safe and effective.

Xanthenones are important biologically active heterocyclic compounds, with remarkable biological and medicinal properties, such as antiviral⁴, anti-inflammatory⁵, antiproliferative⁶ and 50 antibacterial activities. Furthermore these compounds are also used as dyes8, as probes for fluorescence-based detection of biomolecules⁹ and in laser technologies.¹¹ Xanthenones are also investigated for agricultural purpose as bactericide agent⁷ and as photosensitizers in photodynamic therapy.¹¹

- 55 Multicomponent reaction (MCR) approaches, using a phenolic compound, aldehydes and 1,3-dicarbonyl compounds under acidcatalyst effect, are used for synthesis of xanthones. 12-14 In the recent years, use of calix[n] arenes as catalyst has received considerable interest in organic synthesis, particularly in MCRs. 15 60 Calix[n]arenes are macrocyclic compounds synthesized by the
- orto-condensation of para-substituted phenols and formaldehyde under base conditions. There are a large number of applications involving calix[n]arenes due to their easy structural modification. 15-17 In the last two decades, chemical literature has numerous applications of calix[n]arenes supramolecular chemistry. 18 Among all calix[n] arenes known so far, p-sulfonic acid calix[n] arenes showed to be the most efficient catalysts for Biginelli¹⁹, Povarov^{20,21}, Mannich-type²² and esterification²³ reactions. Although the use of calix[n] arenes as
- 70 catalysts in various reactions, there is no report in the literature on the use of these compounds as catalysts in the synthesis of xanthenones.

The facilite synthesis based on MCR approaches and the diverse biological profile exhibited by xanthenones brought new perspectives for the development of new drugs based on this class of compounds. Herein, we report the synthesis of fifty-nine xanthenones and their *in vitro* antiproliferative activity was investigated on six human cancer cell types and some structure—activity relationship (SAR) studies were conducted.

10 Results and Discussion

Published on 16 January 2015. Downloaded by University at Buffalo Libraries on 16/01/2015 19:30:59.

We report herein an easy-to-do and solvent-free three-component synthesis of xanthenones in the presence of a catalytic quantity of the calix[n]arenes **CX1-CX6** (Figure 1). Xanthenones were synthesized using aldehydes, 1,3-dicarbonyl compound, β 15 naphthol or sesamol as a starting material. First we focused on the screening of a series of calix[n]arenes (Figure 1) as catalysts in reactions containing β -naphthol, 4-fluoro-benzaldehyde and dimedone at 120 °C under solvent-free conditions (Table 1). Among the calix[n]arenes tested in the range of 0.15-2.0 mol%, 20 **CX3** and **CX6** were the most efficient catalysts. Both **CX3** and **CX6** at 1.5 mol% furnished the xanthenone **4** in 74% and 68% yields, respectively (Table 1; entries 5 and 10, respectively).

25 **Figure 1.** Struture of calix [n] arenes evaluated as catalyst.

Amounts of **CX3** or **CX6** lower than 1.0 mol% (Table 1; entries 2 and 3 for **CX3**, and entries 7 and 8 for **CX6**) or higher than 1.5 mol% (Table 1; entries 6 and 11, for **CX3** and **CX6**, respectively) 30 provided 4 in poor to moderate yields. The yield of reactions in the presence of 1.5 mol% calix[n]arenes **CX1**, **CX2**, **CX4** or **CX5** was comparable to that of catalyst-free reactions (Table 1; entry 1).

We also evaluated whether calix[n]arenes CX3 or CX6 could be reused in such reactions. After completing the reaction, CHCl₃ and water were added to the mixture for recovering CX3 or CX6 in the aqueous phase from the reaction medium. Once dried, the residue was used in successive reactions in which the yields were monitored. CX3 and CX6 were successfully used in three successive reactions without significant loss of catalyst activity (Figure 2).

Table 1. Effect of the quantity of p-sulfonic acid calix[n]arenes of xanthenone **4** based on the amount of catalyst.

15			•
Entry	(Catalyst (mol%)	Yield ^a (%)
1			16
2		CX3 (0.15)	53
3		CX3(0.5)	57
4		CX3 (1.0)	61
5		CX3 (1.5)	74
6		CX3 (2.0)	63
7		CX6 (0.15)	54
8		CX6(0.5)	61
9		CX6 (1.0)	64
10		CX6 (1.5)	68
11		CX6 (2.0)	67
Reagents	and	conditions:	β -naphthol/4-fluoro-

Reagents and conditions: β-naphthol/4-fluorobenzaldehyde/dimedone (molar ratio of 1.2:1.0:1.5), 120 °C for 1 h. ^aIsolated yield.

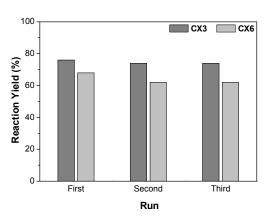

Figure 2. Reuse of *p*-sulfonic acid calix[n] arenes **CX3** and **CX6** in the synthesis of xanthenone **4**.

Considering that yields of reactions in the presence of either **CX3** or **CX6** were roughly the same (Table 1, entries 5 and 10, respectively) we chose the former to evaluate the scope of *p*-ss sulfonic acid calix[4]arene for the synthesis of xanthenones. Thus, a variety of aldehydes, 1,3-dicarbonyls and two phenolic compounds were used (Table 2). Fifty-nine xanthenones (4-62) were synthesized with yields in the range of 58 to 92%. The reaction yields were not considerably affected by the presence of electron-withdrawing or electron-donating groups in the aldehydes (Table 2).

Table 2. Synthesis of xanthenones catalyzed by the *p*-sulfonic acid calix[4]arene **CX3**.

Published on 16 January 2015. Downloaded by University at Buffalo Libraries on 16/01/2015 19:30:59.

Reagents and conditions: phenolic compound/aldehyde/1,3-dicarbonyl compound (molar ratio of 1.2:1.0:1.5), 120 °C for 1 h. The yield for obtaining each xanthenone is presented in parentheses.

61 (71)

60 (84)

sonce synthesized, the structural characterizations of the xanthenones were determined from the corresponding IR, NMR (¹H and ¹³C) and ESI-HRMS data. Crystals of **4** were also obtained and its crystal structure was determined using single-crystal X-ray diffractometry. Crystal data and refinement results are provided as supporting information (Table S1). Xanthenone **4** crystallizes in the triclinic system (space group P1). Both *R* and *S* enantiomers are present in the chosen crystallographic asymmetric unit (Figure 3). Their molecular conformation is similar. Moreover, they can not be related by centrosymmetry in

59 (89)

in the centrosymmetric triclinic space group with only one molecule in the asymmetric unit. The xanthenone core, formed with the four fused rings labeled as A-D in Figure 3, is approximately planar, except for ring A which assumes a half-20 chair conformation with C3 deviating away from the least-squares plane calculated through the other five coplanar atoms of this ring by -0.631(7) Å in the *R*-enantiomer (atom labels ending with suffix A) and 0.660(6) Å in the *S*-enantiomer (atom labels ending with suffix B) (r.m.s.d. of the C2-C1-C6-C5-C4 fitted

ARTICLE TYPE

atoms is 0.0292 Å in the R-enantiomer and 0.0205 Å in the Senantiomer). Ring B is not completely planar in both enantiomers, with C7 carbon deviating by -0.270(6) Å in the Renantiomer and 0.212(6) Å in the S-enantiomer from the leasts square mean plane calculated through the C6-C5-O2-C9-C8 atoms (r.m.s.d. of the fitted atoms is 0.0431 Å in the Renantiomer and 0.0270 Å in the S-enantiomer). Taking the xanthenone mean plane is taken as reference, the out-of-plane C3 and C7 carbons are on the same side of the fluorinated phenyl 10 ring in both enantiomers. Another intramolecular feature common to both enantiomers is the substituted phenyl ring conformation. Ring E is almost perpendicular to the xanthenone mean plane, forming an angle of 82.04(12)° in the R-enantiomer and 84.33(17)° in the S-enantiomer with the least-square plane 15 calculated through the planar non-hydrogen atoms of the four fused rings A-D. Therefore, C3 and C7 were not included in this mean plane calculation.

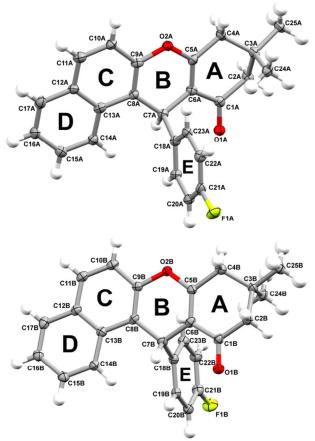

Figura 3. The two crystallographically independent molecules of compound 4. Ellipsoids of 30% probability and arbitrary radius spheres represent non-hydrogen and hydrogen atoms, respectively. Rings are also arbitrarily labeled.

Antiproliferative activity

Although xanthenones are known as bioactive heterocyclic compounds, only few works explored the potential of this class of compounds against cancer cells. Based on this, the antiproliferative effect of a series of synthesized xanthenones were investigated on glioma (U251), breast (MCF-7), multiple drugs-resistant ovarian (NCI-ADR/RES), renal (786-0), lung nonsmall cells (NCI-H460), colon (HT-29), and keratinocyte (HaCaT). Cell proliferation was determined by the sulforhodamine B method and doxorubicin (Dox) used as a positive control.²⁴

Initially the fifty-nine xanthenones synthesized were subdivided into two groups of compounds according to the precursor phenol structure. Group 1 was constituted of β-naphthol-derived xanthenones (4-32; Table 2) while 33-62 (Table 2), sesamol derivatives, were included in Group 2. The concentration of the most active xanthenones that elicited 50% cell growth inhibition (GI₅₀) is summarized in Table 3. The GI₅₀ values for the remainder compounds tested are provided as supporting information (Table S2).

⁴⁵ When analyzing the data obtained for compounds of Group 1 (Table 3) noted that the NCI-ADR/RES cell line was the most sensitive cancer cells as attested by the number of compounds that negatively affected cells growth at $GI_{50} \le 10 \mu g/mL$ (Table 3). NCI-H460 cells were the least sensitive to compounds of Group 1 (Table 3).

For NCI-ADR/RES nineteen compounds of Group 1 showed GI₅₀ values lower than 10 µg/mL. The active compounds of Group 1 for this strain showed GI₅₀ values in the range of 0.027 to 9.8 μg/mL. Among the active compounds of Group 1 for NCI-55 ADR/RES cell line compound 5 was the most potent, with an GI₅₀ value of 0.027 μg/mL, its GI₅₀ value was found to be in the same order of magnitude of that for doxorubicin ($GI_{50} = 0.047$ µg/mL) (Table 3). Indeed, xanthenone 5 showed high selectivity index for NCI-ADR/RES cancer cells, presenting weak 60 antiproliferative activity against non-tumorogenic HaCat cells (Table 3). Xanthenones 7, 9, 13, 15, 16, 23 and 29 were also promising against NCI-ADR/RES cells by exhibiting GI₅₀ around 1 μg/mL (Table 3). Xanthenones 13, 15, and 29 were the most potent compounds against NCI-H460 cells; its GI₅₀ value were 65 lower than 5.0 µg/mL. MCF7 cells were highly sensitive to xanthenones 8, 9, 13-15, 24 and 29 (Table 3). Compounds 13-15, 20 and 29 compromised U251 cells growth by 50% when used at concentrations lower than 6.5 µg/mL, while 786-0 cells were sensitive to 4, 6, 8, and 29. For HT-29 cells compounds 13-15, 70 and 29 were the most potent with GI₅₀ values lower than 4.0 μg/mL. Among the tested compounds of Group 1, xanthenones 13, 15, 29 were those that exhibited the largest

spectrum of action. These xanthenones showed considerable antiproliferative activity ($GI_{50} < 10 \mu g/mL$) against all the cancer cell lines, except for kidney cancer cell line (786-0) in which xanthenones **13** and **15** presented GI_{50} values of 216.0 and 29.8 $_{5}$ $\mu g/mL$, respectively (Table 3).

The second group of xanthenones evaluated (Group 2) is related with those compounds derived from sesamol (Table 3, compounds 33-62). The antiproliferative activity of these compounds was expressed as the concentration that produced 10 50% cell growth inhibition or a cytostatic effect (GI₅₀, μg/mL) for each cell line (Table 3). Data obtained for compounds of Group 2 (Table 3) shows that MCF7 was the most sensitive cancer cells as attested by the number of compounds that negatively affected cells growth at $GI_{50} \le 10 \mu g/mL$. Nine compouds were active agaist MCF7, and 48 was the most potent with GI_{50} of 0.7 μ g/mL. Compounds 48 also compromised U251, NCI-ADR/RES, and HT-29 cells growth by 50% when used at concentrations lower than 1.0 µg/mL while NCI-ADR/RES cells were sensitive to other six compounds 36, 39, 41, 43 e 45, and 49. For HT-29 cells 20 compounds 41, 45, 49 and 56 were the most potent with GI₅₀ values lower than 4.0 µg/mL. Kidney cells (786-0) was the less sensitive strain to compounds of Group 2, for this line only compounds 41, 48 and 49 were active, with GI₅₀ values of 4.0, 2.2 and 7.1 µg/mL, respectively. For NCI-H460 strain 25 compounds 41, 48, 49 and 56 were active compounds of Group 2. Compounds 48 (GI₅₀ = 2.3 $\mu g/mL$) and 56 (GI₅₀ = 3.1 $\mu g/mL$) exhibited GI₅₀ values lower than 4.0 µg/mL, thus showing potent anticancer activity. Among compounds of Group 2, 41, 48 and 49 were that showing the highest spectrum of action, which were 30 active against the six cancer cell lines evaluated. Compound 48 showed GI₅₀ values lower than 4.0 µg/mL for all tested strains and can therefore be described as the most promising compound among compounds of Group 2.

The selectivity index (SI) was calculated for each compound of Group 1 and 2 (Table 3). Among evaluated xanthenones, compound 5 showed the highest SI value for NCI-ADR/RES cells, which indicated the potential use of this compound for future *in vivo* tests.

When compared the results obtained for compounds of Group 1 and 2, we can see that in general compounds of Group 1 were more active than the compounds of Group 2. Among compounds of Group 1 evaluated eight compounds showed no activity against any of the tested strains, where eigheteen compounds of Group 2 were inactive for all cell lines evaluated. Together these results suggest that the naphthyl nucleus is important for the antiproliferative activity of this class of compound. Overall, the potency of xanthenones was dependent on the histological origin of cancer cells.

50 QSAR Studies.

Published on 16 January 2015. Downloaded by University at Buffalo Libraries on 16/01/2015 19:30:59.

For a more careful analysis of the relationship between molecular structure and biological activity, QSAR studies were performed. To determine the correlation between molecular descriptors and the efficiency of the set of xanthenones, we tested a set of models as discussed below.

At first, a structural analysis of the studied compounds was carried out. The geometries of the 59 synthesized compounds of were obtained from AM1 semiempirical calculations, after a conformational analysis using the conformer distribution subroutine of the SPARTAN'06 software. The most stable conformation of each derivative was then reoptimized with the MOPAC software, again using the AM1 method. The outputs files from the MOPAC calculation were used to generate a set of molecular descriptors by using the CODESSA software.

CODESSA may generate about 400 molecular descriptors associated with molecular constitution, geometry, and topology and with electrostatic, thermodynamic, and quantum chemical parameters. The molecular descriptors generated by CODESSA were correlated to the biological efficiency using the heuristic method. ²⁵ Models based on a single molecular descriptor were chosen to obtain statistically significant meanings. After elimination of descriptors with low variance or high intercorrelation, the best correlations were found with the molecular descriptors for compounds of Group 1 to cell lines U251 and NCI-H460. Compounds with GI₅₀ > 250 μg/mL were not considered in QSAR studies.

For U251 the best correlation was between experimental biological activity of compounds of Group 1 and the calculated efficiency based on the molecular descriptor HDCA-1.

HDCA-1 is a molecular descriptor that reports the hydrogen bonding donor ability of the molecule. The values of this descriptor are obtained as a sum of the accessible surface area of H-bonding donor H atoms, as described below.^{26,27}

$$HDCA1 = \sum_{D} s_{D}$$
 $D \in H_{H-donor}$

where

 $s_{\rm D}$ – solvent-accessible surface area of H-bonding donor H atoms.

The model obtained for U251 cells is given in Figure 4 with the corresponding calculated *versus* measured efficiency plots.

This correlation indicates that the increasing the accessible surface area of hydrogen bond donor atoms (*HDCA1*) leads to an increase in biological activity of the compound. This model shown to be consistent with the fact that compounds 13, 14, 15, and 29 which have a hydroxyl group in the *meta* or *para* position and have the highest values of HDCA1 molecular descriptor were the most active against U251 cells. Although compounds 11 and 21 possess a hydroxyl group in the *ortho* position, this is less accessible than the *meta* or *para* positions resulting in lower values for the descriptor HDCA1 and experimental biological activity.

10 Figure 4. Experimental versus calculated efficiency with the HDCA1 descriptor.

The best correlation found for NCI-H460 cells was between the experimental biological activity of compounds of Group 1 and 15 the calculated efficiency based on the molecular descriptor HDCA2. HDCA2 is a molecular descriptor based on accessible area of hydrogen-bond donor atoms and correspondes to partial

charges.^{26,27} HDAC2 descriptor can be calculated as described

below.
$$HDCA2 = \sum_{D} \frac{q_{D} \sqrt{s_{D}}}{\sqrt{S_{tot}}}$$
 $D \in H_{H\text{-donor}}$

20 where

s_D - solvent-accessible surface area of H-bonding donor H atoms q_D - partial charge on H-bonding donor H atoms S_{tot} -total solvent-accessible molecular surface area

25 The model obtained for NCI-H460 cells is given in Figure 5. This relation indicates that the activity values increase when increasing the value of the molecular descriptor HDCA2. This behavior is similar to that shown for U251 cells and the HDCA1 molecular descriptor. Again compounds 13, 14, 15, and 29 which have a 30 hydroxyl group in the *meta* or *para* positions and have the highest values of HDCA2 molecular descriptor were the most active against NCI-H460 cells and orto hidroxilated compounds 11 and 21 were less activite than meta or para hidroxilated derivatives. In summary these two models shows that the activity of compoouds 35 of Group 1 against U251 and NCI-H460 increased with the increasing in accessible surface area of hydrogen bond donor atoms.

$$Log \left(\frac{I}{IC_{50}}\right) = 4.00e + 00(\pm 5.06e - 01)(HDCA2) - 2.74e + 00(\pm 1.39e - 01)$$

$$n = 22; r^{2} = 0.758; F = 62.5; s^{2} = 0.159; R^{2}_{cv} = 0.639$$

$$0.50 - 0.50 - 0.50 - 0.50 - 0.50 - 0.50 - 0.00 - 0.50 - 0.00$$

5 Conclusions

Published on 16 January 2015. Downloaded by University at Buffalo Libraries on 16/01/2015 19:30:59.

An efficient method was described for the synthesis of fifty nine xanthenones under mild conditions. The reaction yields dramatically increased upon the use of p-sulfonic acid $\operatorname{calix}[n]$ arenes as catalysts. Some advantages of the approach here 10 described include absence of solvents and metal catalysts, short reaction time, catalyst tolerance of a wide range of functional groups and catalyst recycling as well. The ability to inhibit the growth of cancer cells were also investigated for synthesized compounds. Compound 5 was as potent as the reference drug 15 doxorubicin against NCI-ADR/RES and present the greater value of SI. Several compounds were shown to be active against different cancer cell lines indicating that the capacity to inhibit cancer cells growth of the xanthenones was dependent on the histological origin of cells. In gereral xanthenones derivates of β -20 naphtol were more active than derived from sesamol. A QSAR study was performed and two QSAR models were obtained for compounds of Group 1 against U251 and NCI-H460 cells and indicated that the biological activity of compounds increased with increasing accessible surface area of hydrogen bond donor atoms. 25 These results show some xanthenones as lead compounds for

Experimental

General methods and materials

obtaining new anticancer agents.

All starting materials were obtained from commercially available sources with high-grade purity and used without further purification. Calix[n]arenes **CX1-CX6** were prepared according to known procedures. Reactions did not require anhydrous conditions. The melting points (uncorrected) of synthesized xanthenones were determined on a Mettler FP 80 HT apparatus. Infrared spectra were recorded on a Perkin Elmer Spectrum One spectrophotometer (KBr). The ¹H and ¹³C-NMR spectra were recorded on a Bruker AVANCE DPX-200 spectrometry at 200 MHz to ¹H and 50 MHz to ¹³C, in DMSO-d₆, CDCl₃ or pyridine-

 d_5 . Coupling constants (J) are reported in Hertz (Hz). High 40 resolution mass spectra (HRMS) were recorded on Shimadzu LC-IT-TOF Prominence system. Low temperature X-ray diffraction data were collected using an Enraf-Nonius Kappa-CCD diffractometer equipped with a CCD camera of 95 mm and κgoniostat. No absorption correction was applied to the raw dataset 45 due to the negligible absorption coefficient using graphitemonochromated Mo K α beam (λ =0.71073 Å). The structure was solved using the direct methods of phase retrieval and the model was refined by full-matrix least squares method based on F². Positions of hydrogens have followed a riding model with bond 50 distances stereochemically constrained according to the bonded carbon. The isotropic thermal displacement parameters of hydrogens were either 20% (C-H hydrogens, except those in methyl moieties) or 50% (hydrogens in methyl moieties) greater than the equivalent isotropic parameter of the bonded carbon.

General procedure for the synthesis of xanthenones

A mixture of an aromatic aldehyde (1 mmol), 1,3-dicarbonyl compound (1.5 mmol) and β -naphthol or sesamol (1.2 mmol) and ρ -sulfonic acid calix[n]arene **CX3** or **CX6** (1.5 mol%) was stirred at 120 °C for 1 h. After completion of the reaction, methanol and was added to the mixture and stirred for 30 min. Then the solid was filtered and washed with cold ethanol to afford the xanthenones **4-62** in high purity (Table 3). All xanthenones were characterized by 1 H, 13 C NMR, IR, HRMS (ESI) and melting point (see Supporting Information for reference).

Antiproliferative assay

Human tumor cell lines U251 (glioma), MCF-7 (breast) NCI-70 ADR/RES (multiple drugs-resistant ovarian), 786-0 (renal), NCI-H460 (lung, non-small cells), HT-29 (colon), and HaCaT (keratinocyte) were kindly provided by Frederick Cancer Research & Development Center-National Cancer Institute-Frederick, MA, USA. Stock cultures were grown in RPMI 1640 75 (GIBCO BRL, Life Technologies) supplemented with 5% of fetal bovine serum and penicillin (final concentration of 1 mg/mL) and streptomycin (final concentration of 200 U/mL). 31,32 Cells in 96well plates (100 µL cells/well) were exposed to Biginelli adducts (0.25-250 µg/mL) for 48 h at 37 °C and 5% of CO₂. Afterward 80 cells were fixed with 50% trichloroacetic acid, submitted to sulforhodamine B assay for cell proliferation quantitation at 540 nm.²⁴ The concentration of compound that inhibits cell growth by 50% (GI₅₀) was determined through non-linear regression analysis using software ORIGIN 7.5 (OriginLab Corporation). 85 Doxorubicin was used as a reference drug. Results presented are from two independent experiments, each done in triplicate.

Computations.

The conformational analysis of the 59 xanthenones was done using the conformer distribution subroutine of the SPARTAN'06 software.³³ The most stable conformation of each derivative was selected for further calculations with the MOPAC code³⁴, again using the AM1³⁵ semiempirical method. In this new step the geometry optimization was developed with the MOPAC code and

ARTICLE TYPE

all structures were confirmed as a local minimum by calculation of the Hessian matrix force constant (no negative eigenvector).³⁶ Two sets of output files were obtained with the MOPAC code. In the first one the following keywords were used: AM1, PRECISE, 5 XYZ, EF, ENPART, VECTORS, BONDS, PI, and POLAR. In the second one, which was used to calculate the thermodynamic properties, the following keywords were used: AM1, PRECISE, THERMO, ROT=1, and XYZ. These output files from MOPAC calculations were used to the development of the initial 10 CODESSA calculations, to generate a set of molecular descriptors used in the QSAR analysis, also developed by using the CODESSA software.37 In the statistical analysis for the QSAR study the following parameters were employed: maximum number of descriptors per model, 1; criterion of significance of 15 parameter, 0.01; level of high correlation, 0.99; level of intercorrelation significance, 0.8.
