The phytosphingosine-containing  $\alpha$ -galactosylceramides ( $\alpha$ -GalCers), KRN7000 and OCH, have been shown to activate NKT cells via interaction with CD1d, a member of the CD1 family of antigen presenting proteins. Evidence from KRN7000 stimulation of NKT cells suggests that α-GalCers may have applications in the treatment or prevention of a range of viral, bacterial, and autoimmune conditions. Moreover, OCH, a truncated analogue of KRN7000, appears to induce a  $T_{H2}$  bias, which could have implications for the treatment of autoimmune and inflammatory conditions. We have prepared the direct sphinganine-containing analogues of KRN7000 and OCH, 1 and 2, and found them to be comparable in activity to the parent compounds in inducing the release of IL-2, IL-4, and IFN $\gamma$ . In addition, compound **2** leads to a cytokine bias similar to that seen with OCH. This is significant because sphinganines are more easily accessed than phytosphingosines, which should facilitate SAR studies.

### Introduction

Studies have identified the CD1 family of proteins as novel, antigen-presenting molecules encoded by genes located outside of those coding for major histocompatibility complexes.<sup>1</sup> CD1d is a member of the CD1 family that has been shown to be an antigen presenting protein for the T cell receptors (TCR) of natural killer (NK) T cells.2-4 CD1d activated NKT cells have been demonstrated to play a role in a variety of immune responses. The  $\alpha$ -galactosylceramide ( $\alpha$ -GalCer), KRN7000, has proved to be an invaluable tool for enhancing under-

standing of the role of CD1d antigen presentation and NKT cell function. Activation of NKT cells in vivo by administering KRN7000 to mice leads to the production of several cytokines, including IFN $\gamma$  and IL-4. KRN7000 stimulation has provided evidence suggesting that NKT cell-mediated pathways may be used to inhibit hepatitis B virus replication<sup>5,6</sup> or protect against diabetes,<sup>7-9</sup> malaria,<sup>10-12</sup> and tuberculosis.<sup>12</sup> A truncated analogue of

KRN7000, OCH, was found to selectively induce IL-4, as opposed to IFN $\gamma$ , and to offer protection in mice against experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis.<sup>13</sup> More recently, OCH has been shown to offer protection against diabetes in NOD mice<sup>14</sup> and against collagen induced arthritis.<sup>15</sup> These results illustrate the importance of the CD1d pathway of immunomodulation, and they also demonstrate the potential for using structural analogues of KRN7000 to modulate the responses of NKT cells in potentially useful ways.

To further elucidate the role of CD1d antigen presentation and NKT cell responses, access to glycosyl ceramide tools is critical. In addition, the development of more extensive libraries of  $\alpha$ -GalCer structural variants would be of great value in searching for compounds with optimal bioactivities for a range of applications. Both KRN7000 and OCH have a phytosphingosine (aminotriol) sphingoid base moiety. The preparation of phytosphingosines is not trivial.<sup>16</sup> In contrast, sphinganines (aminodiols) are generally more readily prepared.<sup>17</sup> If sphinganine-containing  $\alpha$ -GalCers were shown to mirror the potency and types of activation seen with phytosphingosine-containing compounds, access to biological tools and targeted structure-activity studies would be more straightforward. In this paper we report the preparation and initial biological evaluation of the direct sphinganine analogues 1 and 2 of KRN7000 and OCH, respectively.

#### **Results and Discussion**

We have recently reported straightforward access to sphinganines and C3 protected sphinganines using serine-

derived Weinreb amide **3** as a template.<sup>18</sup> Thus, the sphingoid bases 8a and 8b required for the synthesis of  $\alpha$ -GalCers 1 and 2 were prepared as shown in Scheme 1. Double deprotonation of 3 with the sacrificial base secbutylmagnesium chloride under conditions previously described, 18,19 followed by addition of *n*-pentadecylmagnesium bromide or *n*-hexylmagnesium bromide (prepared from the corresponding alkylbromides), provided aminohydroxyketone 4a or 4b, respectively. Silyl protection of **4** gave ketones **5**. Diastereoselective reduction of **5** with lithium tri-tert-butoxyaluminum hydride under conditions described by Hoffman<sup>20</sup> produced *anti*-alcohols **6** in excellent yields. Benzyl protection of the secondary alcohol, followed by cleavage of both the Boc and silvl protecting groups with trifluoroacetic acid (TFA), gave the required protected sphinganines 8a and 8b.

The modest yield in the benzylation of **6** was found to be a result of migration of the TBDMS moiety (~30% migration) to the secondary alcohol (giving **7**') under the reaction conditions. Although **7a** could be separated with difficulty from **7a**' (and **8a** could be readily separated from **8a**'), **7b** and **7b**' were essentially inseparable, as were **8b** and **8b**'. However, following acylation (Scheme 3), pure **11b** was easily isolated. The yield quoted for **7b** is based on the <sup>1</sup>H NMR ratios of **7b/7b'** (2:1) and the combined isolated yield (86%). We have found that the unwanted migration of the silyl group can be circum-

vented by employing TBDPSCl, rather than TBDMSCl, as illustrated for the conversion of **4a** to **8a** in Scheme 2. Thus, after protection of **4** with a TBDPS group, reduction and benzylation of **9** proceeded in a straightforward manner. No significant silyl migration was observed in the benzylation step. One-step cleavage of the silyl- and Boc-protecting groups of **10** was achieved by using in situ generation of HCl.

Sphinganines 8 were converted to  $\alpha$ -GalCer analogues 1 and 2 as shown in Scheme 3. Compound 8a was acylated with the *p*-nitrophenyl (PNP) ester of hexacosanoic acid, and 8b was similarly reacted with the corresponding ester of tetracosanoic acid. The resulting ceramides 11a and 11b, respectively, were glycosylated with use of  $\beta$ -tetrabenzylgalactosyl fluoride in the presence of silver perchlorate and tin(II) chloride. Although the  $\alpha$ -selectivity was high, the yields were low. Global deprotection of 12a and 12b provided analogues 1 and 2, respectively.

In identifying KRN7000 as a lead clinical candidate several related sphinganine analogues were prepared and assayed.<sup>21,22</sup> Although the sphinganine-containing compounds showed tumor inhibitory properties and comparable abilities to stimulate mouse spleen cells, they were not as potent as the aminotriols. More recently, two of the Kirin aminodiols (C24 acyl/C18 sphinganine and C14 acyl/C16 sphinganine) were assayed for their ability to induce the release of IL-2 in mouse  $V_{\alpha}14^+$  NKT cell hybridomas,<sup>23</sup> a response more directly related to CD1d-

mediated effects. The longer chain sphinganine-containing  $\alpha$ -GalCer elicited a greater level of response than the shorter analogue, but not as great a response as KRN7000, consistent with the trend seen in evaluation of T cell proliferation. However, the direct analogue 1 of KRN7000 was not evaluated.<sup>24</sup> Moreover, in efforts to gain an understanding of the role of CD1d in immune responses, it is also appropriate to evaluate other markers related to NKT-mediated responses. Since KRN7000 is the  $\alpha$ -GalCer used most widely in studies related to CD1d, and since OCH has been shown to display both similarities and differences compared to KRN7000, we decided to compare the sphinganine analogues 1 and 2 of KRN7000 and OCH for their ability to induce the release of IL-2, IL-4, and IFN $\gamma$ . These cytokines are well-known products of activated NKT cells and are frequently used in evaluating  $\alpha$ -GalCers.

KRN7000 was available to us, and OCH<sup>25</sup> was prepared by using a combination of literature procedures, as shown in Scheme 4. Garner's aldehyde **13**, prepared in three steps as described by Taylor and co-workers,<sup>26</sup> was converted by minor modifications of the procedure of Imashiro et al.<sup>27</sup> to *ribo*-phytosphingosine **14**. Acylation gave OCH ceramide **15**. Following an approach similar to that used by Savage and co-workers in preparing a biotinylated KRN7000 from its ceramide,<sup>28</sup> global protection of **15**, followed by selective deprotection and glyco-

sylation gave protected OCH **16**. Conversion to OCH was achieved by a two-stage deprotection.

IL-2 production is typically measured to assess the relative abilities of preparations of α-GalCers to stimulate immortalized NKT cells (NKT cell hybridomas). The relative potencies of KRN7000, OCH, 1, and 2 were measured with use of the V<sub>a</sub>14<sup>+</sup> iNKT hybridoma DN3A4-1.2 and three different CD1d-expressing antigen presenting cells: A20.mCD1d (a B cell lymphoma), RMA-S.mCD1d (a lymphoma), and JAWS II (a myeloid/ dendritic cell line). IL-2 production was measured by ELISA from co-cultured supernatants of the hybridoma and one of the three antigen presenting cells previously pulsed with varying amounts of lipid. The relative potencies of the lipids (based on reciprocal effective concentrations for half-maximal response,  $1/EC_{50}$ ) in the presence of the RMA-S and JAWS II antigen presenting cells (APC's) showed the sphinganine analogues 1 and 2 to be essentially as potent as the parent phytosphingosine-containing α-GalCers, KRN7000 and OCH (Figure 1). Moreover, the shorter chain analogue 2, like the corresponding OCH, was slightly less effective at eliciting IL-2 release than KRN7000. Similar results were obtained by using A20.CD1d APCs, with all of the compounds showing potent stimulation of NKT cells, even in the 100 nM range (see the Supporting Information). Thus, with respect to this assay for NKT cell activation, the more easily accessible sphinganine-containing α-Gal-Cers mirrored the activities of the corresponding phytosphingosine-containing compounds.

These results are interesting in light of recently published structural studies.<sup>29,30</sup> Zajonc et al. recently reported a crystal structure of mouse CD1d in complex with a variant of KRN7000 shortened in the acyl chain. Crucial H-bonding interactions were seen between CD1d residue Arg79 and the 3'-OH of the phytosphingosine,

IL-2 levels were fitted to 4-parameter dose/response curves. and residue Asp80 showed H-bonding with both the 3'and 4'-OH's of the phytosphingosine. However, given the similar responses of NKT cell hybridoma DN3A4-1.2 to sphinganine analogues **1** and **2** compared to their phytosphingosine counterparts, it is evident that the interaction with the 4'-OH is not crucial to activity. It is noteworthy that an analogue lacking both the 3'- and 4'-OH's on the sphingoid base has been shown to be inactive.<sup>23</sup>

Immortalized T cell hybridomas tend to produce IL-2, regardless of the cytokines that were produced by the parent cell they were derived from. Therefore, assay of the activation of T cell hybridomas, including those derived from NKT cells, is generally restricted to measurement of IL-2 secretion. By contrast, primary NKT cells from mice and humans tend to produce IL-4 and IFN $\gamma$  when stimulated, plus a variety of other cytokines and chemokines that have been less well studied. T cell cytokine responses have been categorized into two broad groups. T<sub>H</sub>1 responses, typified by the release of IFN $\gamma$  and several other cytokines, are important for fighting

intracellular infections by bacteria and viruses, and overexuberant T<sub>H</sub>1 responses are typical of several autoimmune diseases. By contrast, the secretion of IL-4 characterizes T<sub>H</sub>2 responses. Although excessive T<sub>H</sub>2 responses can cause allergy, they are important for stimulating humoral immune responses and for the elimination of several protozoan parasites. OCH, truncated in both the acyl chain and sphingoid base in comparison to KRN7000, generated intense interest because, although it was not as potent as KRN7000 in inducing NKT cell responses, it consistently induced a T<sub>H</sub>2 bias of NKT cell cytokine responses, as reflected in the proportionately larger production of IL-4 in comparison to  $IFN\gamma$ .<sup>13</sup> In the phytosphingosine series, recent results appear to demonstrate that shortening of either the acyl or the sphingoid base chains induces a  $T_{\rm H}2$  bias.  $^{31,32}$  This suggests that OCH or related compounds (i.e., those that elicit an increased ratio of IL-4 to IFN $\gamma$  secretion) might be potential chemotherapeutic agents for autoimmune or inflammatory conditions mediated by T<sub>H</sub>1 cytokines, as T<sub>H</sub>2 cytokines can inhibit production of T<sub>H</sub>1 cytokines and in some cases reverse their effects. Moreover, ready access to compounds that further probe this hypothesis would be timely. To examine the effects of the sphinganine compounds on the production of cytokines by NKT cells, we measured the levels of IL-4 and IFN $\gamma$  in supernatants of mouse splenocytes cultured in the presence of the various  $\alpha$ -GalCer analogues. Sphinganine analogues 1 and 2, although not as potent, paralleled the parent phytosphingosines in their production of IL-4 and IFN $\gamma$  (Figure 2). There was an indication of a T<sub>H</sub>2 bias of both OCH and 2 in comparison to the longer chain variants. For example, at the 100 nm dose, the ratio of IL-4 to IFN $\gamma$  production with OCH or **2** was approximately twice that observed for KRN7000 or 1 (Figure 2). This was consistent with the similar degree of  $T_{\rm H}2$ cytokine bias that has been seen in vitro in other studies.<sup>13,31,32</sup> It should be noted that previous studies of the  $T_{\rm H}2$  skewing effect of some  $\alpha$ -GalCer analogues have shown that this effect tends to be more pronounced in

vivo when analyzed by injection of compounds into mice and measurement of serum cytokine levels.  $^{32,33}$ 

In summary, the results reported here support the utility of sphinganine-containing  $\alpha$ -GalCers for examining the role of  $\alpha$ -GalCer analogues in modulating immune response. The sphinganine-containing compounds are more readily prepared. Although not quite as potent as the corresponding phytosphingosine-containing  $\alpha$ -GalCers in some assays, such as the in vitro splenocyted stimulation assay, 1 and 2 mirror these compounds in the cytokine responses elicited.

Antigen Presentation Assays. Bulk splenocytes were isolated from normal, 8-12 week old female C57BL/6 mice (Jackson Labs). Cells were plated at 300 000 per well in 96well flat-bottom tissue culture plates in 200  $\mu$ L complete medium: RPMI-1640 supplemented with 10 mM HEPES, 2 mM L-glutamine, 0.1 mM nonessential amino acids, 55  $\mu$ M 2-mercaptoethanol, 100 U/mL of penicillin and 100 µg/mL of streptomycin (Gibco), and 10% heat-inactivated fetal calf serum (Gemini). Cultures contained varying doses of glycolipids, diluted from 100  $\mu$ M stocks in 100% DMSO. After 48 h in a 37 °C, 5% CO<sub>2</sub> humidified incubator, cell-free supernatants were collected and assayed for mouse IL-4 and IFN $\gamma$  content, using standard sandwich ELISA. Capture and biotinylated antibodies were obtained from BD Pharmingen, cytokine standards from Peprotech, streptavidin-horseradish peroxidase from Zymed, and TMB-turbo substrate from Pierce. Absorbance at 450 nm was monitored with a microplate reader (Titertek).

Alternatively, lipid presentation by CD1d was tested by using a hybridoma-based assay. The CD1d-transfected RMA-S.mCD1d clone was provided by Dr. S. Behar.<sup>35</sup> The V<sub>α</sub>-14<sup>+</sup> iNKT hybridoma DN3A4-1.2 has been described previously.<sup>36</sup> Both clones were maintained in complete RPMI medium as above. The CD1d<sup>+</sup> mouse dendritic cell line JAWS II was obtained from the American Type Culture Collection and maintained in MEMa medium with ribonucleosides, deoxyribonucleosides, 4 mM L-glutamine, 1 mM sodium pyruvate (Gibco), 20% heat-inactivated fetal calf serum, and 5 ng/ mL mouse GM-CSF (Peprotech). Antigen presenting cells were plated at 50 000 per well on 96-well flat bottom plates in complete RPMI medium with varying amounts of glycolipids for  $\dot{6}$  h at 37 °C. The cells were then washed three times with PBS (430g, 3 min). These were then fixed with 0.05% glutaraldehyde in PBS (grade I, Sigma) to prevent further antigen processing or loading, followed by quenching with 0.2 M L-lysine (pH 7.4) for 2 min and washes in complete medium. Fifty thousand iNKT hybridoma cells were then added in 100  $\mu$ L complete medium for 12 h. Cell-free supernatants were collected and tested for the presence of IL-2 by ELISA. Antibodies were obtained from BD Pharmingen, mouse IL-2

cytokine standard from R&D Systems, streptavidin-alkaline phosphatase from Zymed, and 4-nitrophenyl phosphate substrate from Sigma. Absorbance at 405 nm was monitored with a microplate reader (Titertek). IL-2 versus logarithm of lipid concentration plots and classical 4-parameter dose/response curves were drawn with Prism 4.02 (GraphPad). Relative potencies of the individual lipids were estimated by the reciprocals of the effective concentrations at 50% maximal response (1/EC<sub>50</sub>).
