Total syntheses of (+)-cytisine, (-)-kuraramine, (-)-isokuraramine, and (-)-jussiaeiine A were achieved via a samarium diiodide-promoted reductive deamination reaction, followed by simultaneous recyclization of a proline derivative to give the corresponding δ -lactam derivative, as a key step.

Introduction

Naturally occurring lupine alkaloids, which have a wide range of structural and stereochemical features, continue to provide challenging synthetic targets.¹ Among them, (-)-cytisine $(1)^2$ has received special attention³ and several synthetic methods have been developed.⁴ since it has been shown to be an important probe in nicotinic acetylcholine receptor research⁵ and shows high affinity at neuronal nicotinic receptors.⁶

are dipiperidine-type alkaloids with two chiral centers at the 3 and 5 positions of the piperidine ring, and are known to be oxidative metabolites of N-methylcytisine. Another dipiperidine-type alkaloid, (+)-isokuraramine $(4)^9$ was also isolated from the fresh flowers of Sophora *flavescens* as a minor constituent, and its structure was determined to be the diastereoisomer of (+)-kuraramine by spectroscopic methods.⁹ However, little attention has been focused on the chiral synthesis of these alkaloids (Figure 1).

Thus, we planned to establish a novel synthetic route to these alkaloids, including cytisine, via a common synthetic intermediate. The key feature of our synthesis is based on a samarium diiodide-promoted reductive

FIGURE 2. Reductive deamination of α -aminocarbonyl compounds.

deamination reaction of an α -amino ester, recently developed by us, as depicted in Figure 2.¹⁰

On the basis of a retrosynthetic analysis of these alkaloids as depicted in Scheme 1, we decided to exploit a readily available 4*R*-hydroxy-L-proline derivative as a starting material to synthesize the enantiomers of the aforementioned natural products, since the use of the antipodal starting material, D-hydroxyproline,¹¹ should lead to the synthesis of natural products if this synthetic strategy can be established.

Results and Discussion

Thus, 4-hydroxy-L-proline methyl ester 5 was converted to the corresponding triflate 8 in three steps. Treatment of 8 with 2-tributylstannyl-6-methoxypyridine **9** in the presence of a palladium catalyst¹² afforded the coupling product 10 in 88% yield. Hydrogenation of 10 over 10% palladium-charcoal in MeOH gave 11, stereoselectively. After the Boc group was removed, samarium diiodide-promoted reductive deamination of the resulting 12, followed by simultaneous cyclization of the resulting δ -amino ester, was carried out in THF-HMPA in the presence of methanol as a proton source to give the desired common intermediate, the δ -lactam 13, in 78% yield.¹⁰ (Scheme 2)

N-Methylation of 13 with iodomethane and sodium hydride in THF-HMPA furnished the corresponding *N*-methylpiperidone **14**, which was further converted into hydroxymethyl derivative as follows.

Treatment of the amide 14 with ethyl chlorocarbonate in the presence of LDA in THF gave an inseparable mixture of diastereomers (15 and 16), in a ratio of ca. 1:1. Reduction of the amide and ester functions of the mixture with LiAlH₄ in THF afforded the amino alcohols ent-3 and 17 in respective yields of 50% and 46%. The spectroscopic data of *ent*-**3** obtained here were identical with those reported for (+)-jussiaeiine A (Scheme 3). Moreover, the sign of the optical rotation of the synthetic compound corresponded to that of the antipode {ent-3, $[\alpha]_{\rm D}$ -5.2 (c 0.5, CHCl₃); lit.⁸ $[\alpha]_{\rm D}$ +3.3 (c 0.26, CHCl₃). Therefore, we were able to establish the first enantioselective synthesis of (-)-jussiaeiine A. Jussiaeiine A (ent-3) was converted into (-)-kuraramine (ent-2) by treatment with iodotrimethylsilane in refluxing acetonitrile.¹³

Again, the physicochemical properties of ent-2 were identical with those reported in the literature, except for the sign of optical rotation¹⁴ {*ent*-**2**: mp 78–80 °C, $[\alpha]_D$ -3.6 (c 2.1, EtOH); lit.⁷ [α]_D +8.4 (c 0.52, EtOH)}.

The same treatment of the diastereoisomeric compound **17** gave isokuraramine *ent*-**4** as an amorphous solid, $[\alpha]_D$ -93.0 (c 2.1, EtOH).⁹

To achieve the total synthesis of (+)-cytisine from the common intermediate 13 through the formation of a carbon-nitrogen bond, as shown in Scheme 4, N-benzylation of 13 and subsequent ethoxycarbonylation of 18 with ethyl chlorocarbonate in the presence of LDA were carried out to provide a mixture of diastereoisomeric β -ketoesters (**19** and **20**) in a ratio of ca. 1:1.

Although the attempted isomerization of the mixture to the thermodynamically more stable 3.5-cis-compound under various reaction conditions, such as basic treatment of a mixture of 19 and 20 with lithium diisopropylamide in THF, sodium hydride in appropriate solvents, and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in benzene, did not improve the ratio, reduction of the mixture with $LiAlH_4$ gave the primary alcohols **21** and **22**, in respective yields of 48% and 43%. Finally, mesylation of 21 followed by thermal cyclization of the mesylate yielded the tricyclic compound 23. Debenzylation of 23 under the hydrogenolysis conditions furnished *ent*-1, whose spectroscopic data were identical with those reported in the literature¹⁵ except for the sign of optical rotation {ent-1: mp 152-153 °C, [α]_D +113.5 (*c* 0.3, EtOH); lit.¹⁶ mp 152–153 °C, lit.¹⁵ $[\alpha]_{\rm D}$ –110 (*c* 0.5, EtOH), lit.^{4e} $[\alpha]_{\rm D}$ –114 (*c* 1, EtOH)}.

In summary, we have established novel and facile syntheses of dipiperidine-type lupine alkaloids, including cytisine. Although these syntheses give the antipodal forms of the natural products, we believe that the strategy developed here should be a useful tool for finding new drugs that are biologically related to cytisine.

To a stirred solution of vinyl triflate (8) (2.12 g, 5.65 mmol) and pyridyl(tributyl)stannane (9) (2.70 g, 6.78 mmol) in THF (30 mL) were successively added tetrakis(triphenylphosphine)palladium(0) (327 mg, 0.283 mmol), lithium chloride (288 mg, 6.78 mmol), and copper(I) iodide (1.29 g, 6.78 mmol) at room temperature under argon. The mixture was heated at 65 °C for 4 h. After being cooled to room temperature, the mixture was diluted with Et₂O and the organic layer was washed with 5% NH₄OH. The aqueous layer was extracted with Et₂O. The combined ethereal layer was washed with brine and dried over Na₂SO₄. Evaporation of the solvent gave a residue, which was subjected to silica gel column chromatography. Elution with hexanes- Et_2O (3:2) afforded the coupling product (10) (1.66 g, 88%) as an inseparable mixture of rotational isomers. $[\alpha]^{25}$ _D -135 (c 1.0, CHCl₃); IR (cm⁻¹) 1755, 1709, 1470, 1433, 1400, 1368, 1346, 1329, 1273, 1257, 1202, 1176 and 1126; ¹H NMR δ 1.46 (5.85H, s), 1.53 (3.15H, s), 3.76 (1.95H, s), 3.77 (1.05H, s), 3.92 (1.95H, s), 3.94 (1.05H, s), 4.58-4.71 (2H, m), 5.15-
