S Supporting Information

ABSTRACT: A rapid synthesis of thiophene-based TAK-779 analogues 1 is reported using a late-stage diversification strategy. At the end of the synthesis, the key building block 2, which was prepared in six steps from thiophene, was arylated regioselectively at the α -position directly with iodoarenes. Since 2 offers several reactive positions, various established

catalyst systems were tested. It was found that Crabtree catalyst (an Ir catalyst) converted efficiently and selectively the thiophene system 2 into 2-aryl-substituted compounds 9. The direct C-H arylation of 2 with electron-rich iodoarenes led to high yields, whereas electron-deficient iodoarenes required longer reaction times for complete conversion. A small set of diverse amides 1 was synthesized by hydrolysis of 9 and subsequent HATU coupling with primary amines 4.

INTRODUCTION

Chemokine receptor 5 (CCR5) antagonists represent a novel class of HIV entry inhibitors. The highly potent CCR5 receptor antagonist TAK-779 is among the most potent CCR5 receptor antagonists reported thus far and can serve as a lead compound for the development of novel antagonists (Figure 1).^{1,2} In this

research program, the benzene ring in the core benzo[7]annulene of TAK-779 is replaced bioisosterically by a thiophene moiety (1). Although thiophene and benzene rings are very similar in size, they differ in electronic and geometric properties, which leads to the modification of pharmacological properties.

Furthermore, the bioisosteric introduction of the thiophene moiety will allow the rapid modification at a late stage of the synthesis by C–H arylation. A large and diverse set of novel ligands 1 will give new information about the complementary binding pocket of the CCR5 receptor protein. In order to obtain a large set of diverse ligands 1, recently emerging C–H arylation technology and subsequent amidation of the key building block 2 are envisaged (Figure 2). This straightforward late-stage diversification strategy would allow us to rapidly generate molecular diversity for CCR5 antagonists 1 by using different iodoarenes 3 and primary amines 4.

RESULTS AND DISCUSSION

The synthesis of ester **2** commenced with a Friedel-Crafts acylation of thiophene with glutaric anhydride and subsequent Wolff–Kishner reduction to afford pentanoic acid **5** in 72% yield.³ Intramolecular Friedel–Crafts acylation of **5** with P₂O₅ required careful optimization of reaction conditions.³ Addition of Celite (5 g/mol) to the reaction mixture to remove water led to a considerable increase of the yield of ketone **6**. Claisen condensation of ketone **6** with dimethyl carbonate provided β -ketoester 7, which was reduced with NaBH₄ (to give **8**) and dehydrated by CH₃SO₂Cl and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) to yield the $\alpha_i\beta$ -unsaturated ester **2** (Scheme 1).

The transition-metal-catalyzed direct transformation of C–H bonds of heteroarenes with haloarenes has been a topic of immense importance during the past decade. In contrast to standard cross-coupling methods such as the Pd-catalyzed Suzuki–Miyaura reaction, the direct C–H bond functionalization can streamline the synthetic process by skipping the premetalation step.⁴ The most common catalysts applied in the synthesis of heterobiaryls by C–H arylation are Pd,^{5–7} Rh,^{8–10}

Cu,¹¹ and Ni¹²⁻¹⁵ complexes. However, it was not easy to identify the right catalyst for the C–H arylation of the thiophene system **2** containing an $\alpha_{,\beta}$ -unsaturated ester moiety.^{16–19}

The PdCl₂/bipy system^{20,21} failed to produce selectively the α -arylated thiophene **9a** with 4-iodobenzene (**3a**), since a mixture of monoarylated products was formed. Variation of the Pd source to PdBr₂²¹ and of the aryl halide to 4-bromotoluene did not improve the selectivity of the transformation. The Pd(OAc)₂/1,10-phenanthroline/Cs₂CO₃ system⁵ led predominantly to diarylated products. The Rh-based catalyst [RhCl-(CO)(P{OCH(CF₃)₂}₃)₂]/Ag₂CO₃⁹ was the least efficient system, leading to several products but only traces of the desired compound **9a**. In addition to the thiophene moiety, the double bond (position 4) and the benzylic position (position 8) of the α,β -unsaturated ester **2** can be attacked by 4-iodotoluene (**3a**) and are therefore responsible for side product formation.

Finally, we identified that cationic iridium(I) complex $[Ir(cod)(py)PCy_3]PF_{67}^{22}$ known as the Crabtree catalyst,^{23,24} can catalyze the regioselective C–H arylation of **2** with 4-iodotoluene (**3a**) (Scheme 2).

Next the reaction conditions for the selective α -arylation using the $[Ir(cod)(py)PCy_3]PF_6/Ag_2CO_3$ system were care-

fully optimized (Table 1). A mixture of thiophene 2, 4-iodotoluene (3a), and $[Ir(cod)(py)PCy_3]PF_6/Ag_2CO_3$ in 1,4-

dioxane was stirred at 170 °C for 12 h. One equivalent of 4iodotoluene and 5 mol % of the catalyst led to an yield of 23% of **9a** (entry 1). Increasing of the amount of 4-iodotoluene up to 1.4 equiv resulted in complete conversion and afforded the monoarylated compound **9a** regioselectively in 93% yield (entry 3). Next the amount of catalyst was investigated; 5.0 mol % as well as 2.5 mol % of the catalyst provided the product in excellent yields (entries 3 and 5). A further reduction of the catalyst amount to 1.0 and 0.5 mol % resulted in significantly lower conversion and yields (entries 7 and 8). Surprisingly, increasing of the reaction scale from 0.48 to 4.8 or even 7.2 mmol of **2** led to dramatically decreased yields of **9a** (entry 4 and 6).

In order to prove the position of the aryl moiety unequivocally, **9a** was recrystallized from acetonitrile to afford crystals suitable for X-ray crystal structure analysis. The X-ray crystal structure reveals clearly that the *p*-tolyl moiety is attached to position 2 of the bicyclic system, indicating that the arylation had taken place selectively at the α -position of the thiophene.

The optimized reaction conditions (1.4 equiv of iodobenzene derivative, 5 mol % of $[Ir(cod)(py)PCy_3]PF_6$, 1.1 equiv of Ag_2CO_3 in 1,4-dioxane at 170 °C for 12 h) were used to

introduce other aryl moieties into the bicyclic thiophene derivative 2 (Table 2). Excellent yields (87–97%) were

obtained with electron-rich alkyl iodoarenes (compounds 9ac). A slightly reduced yield of 78% was obtained in the arylation of 2 with biphenylyl iodide (9d). Despite its high electron density, *tert*-butyl iodobenzene led to only 55% of arylated product 9e. In contrast to electron-rich iodobenzenes, electrondeficient analogues such as 4-trifluoromethyl- and 4-nitrosubstituted iodobenzenes gave reduced yields of arylated products 9f and 9g. However, lengthening the reaction time from 12 to 48 and 72 h increased the yield of 9f from 21% to 41% and finally to 55%. The surprising reduced reactivity of electron-deficient iodoarenes can be compensated at least partially by lengthening of the reaction time.

Although the mechanism of this transformation remains unclear, we assume a concerted metalation deprotonation (CMD) mechanism^{25–27} (Scheme 3). At first an Ir(III) complex is formed by oxidative addition of the aryl iodide to the Ir(I) complex of Crabtree catalyst (step **A**). Next, Ag₂CO₃ removes iodide and releases the base CO₃²⁻, which is able to coordinate with the Ir center to generate the Ir(III)-carbonate complex (step **B**). After coordination of the thiophene to Ir(III) of the metal complex (step **C**), a simultaneous metalation and deprotonation in α -position of the thiophene ring by carbonate occurs (step **D**). Reductive elimination of Ir(I)-complex regenerates the catalyst and provides the biaryl product (step **E**).

In order to prepare the final amides 1, selected esters 9 were hydrolyzed with NaOH, and the resulting acids 10 were subsequently coupled with various amines. Scheme 4 shows that various esters 9 can be combined with various amines 4 to give a diverse set of amides 1aA-1cC.

CONCLUSION

A strategy to introduce diversity at the end of the synthesis to generate thiophene-based TAK-779 analogs **1** has been realized. The central building block **2** containing an α,β -unsaturated ester was structurally diversified by two transformations: thiophene C–H arylation and amide formation. First, the arylation of annulated thiophene **2** was achieved by

the Ir-based Crabtree catalyst, which was superior to established Pd catalysts with respect to regioselectivity and yield. It was shown that electron-rich iodoarenes give high yields of α -arylated compounds 9, whereas the coupling of electron-deficient iodoarenes required longer reaction times. Second, the resulting esters 9 were transformed into diverse amides 1, showing the potential of the late-stage diversification strategy.

Methyl 2-(3-Methylphenyl)-7,8-dihydro-6H-[7]annuleno[b]thiophene-5-carboxylate (9b). A 20 mL glass vessel was equipped with a magnetic stirring bar and closed by a J. Young O-ring tap. The flask was flame-dried under vacuo and filled with N2. Under a permanent flow of N₂, ester 2 (300 mg, 1.44 mmol), Crabtree catalyst (58 mg, 0.072 mmol, 5 mol %), Ag₂CO₃ (442 mg, 1.6 mmol, 1.1 equiv), and 3-iodotoluene (3b, 440 mg, 2.01 mmol, 1.4 equiv) were suspended in dry 1,4-dioxane (14 mL). The vessel was sealed with the O-ring tap and heated to 170 °C for 12 h in a 8-well reaction block. After the vessel cooled to rt, the mixture was filtered through a short silica pad (EtOAc). The filtrate was concentrated in vacuo to give the crude product as a brown oil, which was purified by flash column chromatography (EtOAc/cyclohexane = 2:8, d = 4 cm, l = 6 cm, V =30 mL) to give a yellow oil, which was recrystallized from acetonitrile to give the ester **9b** as a pale yellow solid.
