Introduction

There are many applications of dyes in biochemistry, imaging, and therapy that require appended, robust biotargeting motifs. Since there is a wide range of biotargeting motifs available for all of these applications, core dye platforms with appropriate photophysical properties that can be rapidly and efficiently appended with the targeting motif avoid the complex redesign of synthetic strategies. Photodynamic therapy (PDT), for example, is a noninvasive treatment for cancer involving the interaction of light, a photosensitizer and oxygen to result in generation of singlet oxygen and other reactive oxygen species that cause necrosis or apoptosis.^{1,2} There are many cancer targeting motifs, including sugars and peptides.

The photophysics of porphyrin and phthalocyanine derivatives can be tuned for many of the above applications. For example, those with good triplet quantum yields can serve as photosensitizers for PDT, while those with good fluorescence quantum yields can serve as imaging agents and biochemical trackers. Thus there

ABSTRACT

A triply bridged fused diporphyrin appended with six thioglucose units is reported. This new, chemically, and photochemically stable amphiphilic compound is taken up by breast cancer cells and causes cell death upon light exposure. Photophysical studies reveal absorption bands in the near IR region, and photosensitized formation of singlet oxygen in high quantum yields.

is a need for a palate of these core dye platforms with different photophysical properties. Porphyrinoids are generally non-toxic under dark conditions.^{3,4} Imaging and PDT of various forms of cancers are more efficient if the dye absorbs light in the therapeutic window (ca. 700–1100 nm) especially for deep cancers,^{5–7} so bio-targeted dye systems with longer wavelength absorptions are needed for next-generation imaging and PDT agents.^{8,9}

Direct, covalent linking of porphyrins (e.g., 2 and 3 in Fig. 1) yields systems with photophysical properties such as high polarizability and high nonlinear optical character¹⁰ that arise from strong electronic coupling of the macrocycles. Compounds such as 1 and 2 are fluorescent. Fused $(\beta - \beta, meso-meso, \beta - \beta)$ triply bridged porphyrins have low energy absorption bands in the infrared region because of extended conjugation and coplanar geometries.¹¹ Compounds such as 3 are minimally fluorescent but exhibit large twophoton absorption (2PA) cross sections (σ) where two low energy 1400-2000 nm photons are simultaneously absorbed and have good triplet quantum yields.^{12,13} Sugar moieties appended to porphyrinoids increase the selective uptake by cancer cells.¹⁴ The number, type, and position of the sugar moieties effect cell uptake,^{15,16} but the hydrolysis of O-glyco linkages of many reported conjugates can diminish in vivo effectiveness compared to non-hydrolysable derivatives.¹⁴

Figure 1. Oxidative coupling of 1 with DDQ/Sc(OTf)₃ yields 2 and 3,¹³ but substitution of the *para* fluoro groups 2 or 3 is inefficient. Adding the sugars to compound 1 proceeds in high yields, followed by oxidative coupling of 4b with PIFA efficiently yields 5a and 6a, which are readily deprotected to yield 5b and 6b.

Table 1UV-visible spectral data for 5b

Solvent	UV-visible λ_{max}^{a} (nm)
DMSO	429, 462, 569, 610, 636, 749, 876, 943, 1090
Toluene	427, 462, 525, 565, 606, 667, 829, 966, 1079
Ethylacetate	428, 462, 524, 565, 606, 671, 848, 952, 1070
PBS	426, 461, 526, 565, 607, 671, 849, 950, 1071
Ethanol	421, 455, 514, 561, 602, 664, 837, 935, 1029, 1078

 $^{\rm a}\,$ 1 cm path length. See ESI. In CHCl_3 the lifetime is 3.3 ps, but no quantum yield is reported (Ref. 13).

Our work on perfluorophenylporphyrins suggests that the triply linked fused diporphyrin bearing six perfluorophenyl groups **5**, and singly bridged derivative **6** (Fig. 1) could serve as platforms to form bioconjugates and biocompatible compounds thereby exploiting the photophysical properties of **2** and **3** reported by Kim and coworkers.^{8,13,17–20} Herein we report the synthesis, optical properties, cell uptake, and photodynamic induced necrosis activity of hexa-glycosylated diporphyrin, **5b**, and the fluorescence imaging properties of **6b**. Since the substitution of all six *para* fluoro groups on **3** and isolation of this product proved difficult, we used the trisperfluorophenyl porphyrin precursor (**1**, Fig. 1) as the platform to append the thiosugars, and then formed the fused porphyrin by a mild oxidative coupling reaction. The generality of the substitution chemistry of **1** affords a platform to append a diversity of conjugates, thereby broadening the applications of the two dimers.

Results and discussion

5,10,15-Tris(pentafluorophenyl)porphyrinatozinc(II) (1) was synthesized using the procedure reported²¹ (Scheme ESI 1), and is the platform molecule for the synthesis of singly and triply linked diporphyrins with diverse biotargeting motifs. The oxidative coupling reported by Osuka used DDQ/Sc(OTf)₃ to form **3**.¹³ Since

the electron withdrawing groups on **1** inhibit the oxidative coupling and DDQ/Sc(OTf)₃ reacts with the sugars, we employed the hypervalent iodine(III) reagent, phenyliodine bis(trifluoroacetate) (PIFA) for oxidative coupling.²² The oxidation of **1** bearing an open *meso* position with different equivalents of PIFA results in the formation of *meso-meso* linked diporphyrin **2** and the β - β , *mesomeso*, β - β triply linked diporphyrins **3** (Scheme, ESI 2).^{23–27} The metal ion chelated by the macrocycle improves the yields.

Porphyrin **1** was treated with 3.5 equiv of thioglucose and then Zn(II) was inserted to efficiently yield **4b**. The glycosylated triply linked compound **5b** is obtained in 40% yield after reacting with 2.5 equiv of PIFA, and 1.2 equiv yield predominately **6a**. The structures of all porphyrinoids were confirmed by ¹H, ¹⁹F and ¹³C NMR spectroscopy, UV–visible, and MALDI-TOF spectra (ESI).

The UV–visible and emission spectra of the glycosylated derivative **5b** and **6b** are similar to those reported for **3** and **2**, respectively.¹³ Because the porphyrins are orthogonal in **6b**, the photophysical properties are similar to *meso* aryl porphyrins and aggregates somewhat less than the fused derivative. However, the UV–visible spectra **5b** exhibit a broad Soret band at 413 nm and Q-bands between 557 nm and 1068 nm; in different solvents because the compound can partition into different cellular environments (Table 1 and ESI). No apparent aggregation of **5b** was observed in DMSO, but in other solvents the compound aggregates as indicated by shoulders on both blue (H-aggregate) and red (Jaggregate) edges of the main absorption peaks.

The aggregation of **5b** was confirmed by dynamic light scattering (DLS) measurements in these solvents (ESI Table 1). The size and structural organization of nanoaggregates of porphyrinoids depend on a variety of factors such as concentration, type of solvent used, temperature, and nature of peripheral groups attached to the chromophore.²⁸ After shaking in phosphate buffered saline (PBS), DLS shows two populations with diameters of 30 ± 4 nm and 284 ± 15 nm, but after sonication for about 15 min, only 82 ± 7 nm particles are observed. The size of the nanoaggregates

Figure 2. MDA-MB-231 cells were incubated with ca. 50 nM of the singly linked dimer **6b** for 24 h, rinsed four times with PBS buffer to remove any unbound dye and fixed with 4% paraformaldehyde solution in NaOH. Fluorescence images were captured using 540–580 nm band pass excitation and 600–650 nm band pass emission, magnification $20 \times$ under identical instrumental conditions. (A) Just after preparation of the fixed cells, and (B) the same slide after 3 days. The contrast in each case was enhanced by 40% for publication.

Figure 3. Top: after treating MDA-MB-231 human breast cancer cells with 5b and 6b for 24 h and removing the unbound dye, dark toxicity of 5b (blue), 6b (green) and phototoxicity of 5b (red) and 6b (orange) upon irradiation of cells with white light (0.92 mW cm⁻²; 11.04 kJ m⁻² for 20 min) were determined using a trypan blue assay. Bottom: the cells continue to become necrotic for the next 18 h after similar treatment with 10 µM of **5b** (black) and **6b** (brown).

and strength of intermolecular interactions significantly affect the endocytosis of the photosensitizer by cancer cells, and the propensity of the dyes to disaggregate while adsorbed on the cell membrane or within the cell. Because fewer dyes are excited and energy transfer processes in aggregates, the effective triplet quantum yield is reduced, thereby reducing the PDT effectiveness.

However, fluorescence microscopy shows that nano-aggregates of 6b are taken up by MDA-MB-231 human breast cancer cells and slowly disaggregates inside the cells as indicated by the increased fluorescence intensity (Fig. 2). Since 5b does not fluoresce, the disaggregation is indicated by the PDT effects, wherein the light may contribute to the disaggregation via internal conversion.

The singlet oxygen quantum yield ($^{1}O_{2}$) production (Φ_{Δ}) for **5b** in DMSO was determined to be 0.78 \pm 0.03 in which the ${}^{1}O_{2}$ phosphorescence at 1270 nm was monitored²⁹⁻³¹ and meso-tetra dihydrochloride (4-sulfonatophenyl)porphyrin (TSPP) was employed as a reference sensitizer (Φ_{Δ} TSPP = 0.63 in D₂O).³¹ Both 5b and 6b were examined for PDT effect on the MDA-MB-231 human breast cancer cells (Fig. 3) where the percent of viable cells is significantly reduced upon light exposure. Irradiation with white light causes necrosis with an IC₅₀ for **5b** of ca. 13 μ M and for **6b** ca. $19\,\mu M$ measured just after photodynamic treatment, and $24\,h$ later, ca. 75% of the cell are necrotic for compound 5b and ca. 66% necrotic for compound **6b**, indicating induction of apoptosis.¹⁴

Conclusion

The mechanism of uptake of non-hydrolysable thioglycosylated porphyrinoids by cancer cells is not well understood. The overexpression of glucose receptors on the cell mediates adsorption to the membrane, but the compounds must diffuse or the nanoaggregates be internalized by endocytosis.³² These two porphyrin dimers add the palate of dyes for platforms for biomedical applications.
