Abstract—Total synthesis of cordiaquinone K, a new antifungal and larvicidal meroterpenoid, is reported. The absolute configuration of cordiaquinone K was confirmed by the synthesis.

Cordiaquinones are antifungal and larvicidal meroterpenoids isolated from Panamanian plants such as Cordia linnaei. In 1990, Messana and co-workers reported the isolation and structures of cordiaquinones A (1) and B (2) (Fig. 1). After their identification of cordiaquinones from the plant, several cordiaquinones have been isolated. In 2000, Hostettmann and co-workers reported the structures of cordiaquinones J (3) and K (4) isolated from C. curassavica (Fig. 1). These compounds exhibit antifungal activities against phytopathogenic fungus such as Cladosporium cucumerinum and larvicidal activity against the larvae of the yellow fever-transmitting mosquito Aedes aegypti. The structures of cordiaquinone J and K were established on the basis of HRMS, UV and 1D and 2D NMR spectra. The synthesis and absolute configuration of cordiaquinone B were reported by Asaoka and his co-workers. The absolute stereochemistry of other cordiaquinones, however, remained unknown. In connection with our synthetic studies of biologically active natural terpenoids, we became interested in clarifying the absolute configuration of cordiaquinones. This communication describes the total synthesis of (+)-cordiaquinone K employing one-pot B-alkyl Suzuki–Miyaura coupling as a key step and the determination of the absolute configuration of the natural product.

As our target, we first chose (+)-13-deoxocordiaquinone K (5), since there was an urgent need to establish the appropriate conditions of the coupling reaction. Scheme 1 summarizes our synthesis of (+)-13-deoxocordiaquinone K (5). 6-Bromonaphthoquinone (6) and (+)-\(\gamma\)-cyclhomogeranol (8) were selected as the starting materials. 6-Bromonaphthoquinone (6) was first hydrogenated with PtO\(_2\) followed by methylation of the resulting hydroxyl groups to give 7.\(^{10}\) (+)-\(\gamma\)-Cyclomogromeriobol (8) was converted to known iodide (9).\(^{6a,11}\) To connect the \(\gamma\)-cyclohomogeranyl unit (9) and the naphthoquinone derivative (7), we examined one-pot B-alkyl Suzuki-Miyaura coupling reaction. This protocol would be useful for the syntheses of terpenoids such as ambrein,\(^{12}\) luffarin W,\(^{13}\) penlanpallescensin,\(^{14}\) etc. (Fig. 2), because these compounds have a common structural feature with cordiaquinone K, namely a \(\gamma\)-cyclohomogeranyl unit connecting with an aryl or a vinyl unit.

As a preliminary experiment for the coupling of 9 with 7, the conditions reported by Marshall and Johns\(^{15,16}\) \{PdCl\(_2\)(dpff) as a catalyst\} were examined to give the desired product (10) in only 10% yield based on 9. Then we examined various conditions. Table 1 summarizes reaction conditions and yields of 10. Although PdCl\(_2\)(dpff) was not an effective catalyst (entries 1–3), Pd(PPh\(_3\))\(_4\) was superior in yield (entry 4). Moreover, by heating the reaction mixture to 80°C, 50% yield of 10 was obtained (entry 6). This indicates that the yield based on 7 was quantitative. Increasing the stoichiometry of 7, however, showed only a slight improvement (55%, entry 7). Other palladium catalysts such as Pd\(_2\)(dba)\(_3\), PdCl\(_2\)(dppe), PdCl\(_2\)(dppp), Pd(PPh\(_3\))\(_2\)Cl\(_2\), Pd(OAc)\(_2\)+2Cy\(_3\)P and allylpalladium chloride dimer or a combination of bases such as Ba(OH)\(_2\), TIOEt and Cs\(_2\)CO\(_3\) were also examined, but we found Pd(PPh\(_3\))\(_4\) with K\(_3\)PO\(_4\) is the best choice for the coupling reaction.

![Figure 2. Structures of natural products with related structure of cordiaquinones.](image)
With the desired product (10) in hand (Scheme 1), the aromatic ring of 10 was oxidized with ceric ammonium nitrate (CAN) to afford (±)-13-deoxocordiaquinone K (5). The spectroscopic data of synthetic 5 are in perfect accordance with the structure of 5.17

According to the established methodology as described above, the synthesis of optically active cordiaquinone K was investigated (Scheme 2). The known alcohol18 (12) derived from the known ketoalcohol (11)19 was selected as the starting material. Alcohol 12 was converted to the corresponding iodide 13 in two steps (96%). The resulting iodide 13 was coupled with 7 by using the optimized conditions to give coupled product 14 in moderate yield (43%). After removal of the TBS group of 14 with TBAF at 60°C (74%), the resulting hydroxyl group was oxidized with PCC to give ketone 15 (63%). Finally, oxidation of the aromatic ring with CAN at 0°C for 30 min gave (S)-(+) -cordiaquinone K (4)20 as a pale yellow gum in quantitative yield. The overall yield of (+)-1 was 19% in six steps from known alcohol (12). The 1H and 13C NMR and MS spectra are identical with those of reported data.4 Synthetic cordiaquinone K (4) shows [α]D26 = +44.9 (c = 0.35, acetone), while natural cordiaquinone K shows [α]D = -46.4 (c = 0.35, acetone).4 This means that our synthetic cordiaquinone K is the antipode of the natural product. The absolute configuration of natural cordiaquinone K is, therefore, determined to be R.

In conclusion, the total synthesis of (+)-cordiaquinone K was achieved by using one-pot B-alkyl Suzuki–Miyaura coupling reaction. The absolute configuration of natural cordiaquinone K was confirmed to be R. Further synthetic studies of other cordiaquinones or terpenoids employing this methodology are in progress.

10. All new compounds gave satisfactory spectral and elemental analytical data (combustion and/or HRMS).
16. Representative procedure for the synthesis of (±)-10: To a stirred and cooled (−78°C) solution of 9 (97 mg, 0.35 mmol) in dry ether (5 ml) was added dropwise 530 μl of tert-BuLi (1.4 M in pentane, 0.75 mmol) under Ar. After stirring for 3 min, 820 μl of B-methoxy-9-borabicyclo[3.3.1]-nonane (1 M in hexane, 0.82 mmol) was added dropwise, followed by addition of dry THF (5 ml). After stirring for 10 min. at the same temperature, the resulting solution was allowed to warm to rt for 75 min. To the mixture, 3 M K2PO4 solution 0.27 ml (0.80 mmol) was added, followed by a solution of 7 (85 mg, 0.32 mmol) in DMF (5 ml). After addition of Pd(PPh3)4 (18 mg, 0.016 mmol), the mixture was stirred at 80 °C for 16 h. After cooling to rt, the mixture was diluted with ether. The organic layer was washed with water and brine, and the combined aqueous layers were extracted with ether three times. The combined organic layers were dried with Na2SO4. After concentration in vacuo, the residue was chromatographed on silica gel (SiO2: 8 g, hexane) to give 65 mg of (±)-10 (55%).
