Abstract

A rapid one-pot solvent-free procedure has been developed for the synthesis of fluorinated 2,3-disubstituted quinazolin-4(3H)-ones by neat three-component cyclocondensation of anthranilic acid, phenyl acetyl chloride and substituted anilines under microwave irradiation. The experimental methodology and microwave conditions described here are well established, allowing significant rate enhancement and good yields compared to conventional reaction conditions. The reaction is generalized for *O*, *M* & *P* substituted anilines to give quinazolin-4(3H)-ones. Synthesized compounds have been screened for their antifungal activity.

Keywords: Quinazolines; Three-component system; Microwave irradiation

1. Introduction

Quinazoline compounds are reported to be physiologically and pharmacologically active and find applications in the treatment of several diseases like leprosy and mental disorder and also exhibit a wide range of activities [1]. A well known methaquolone [2] having quinazoline nucleus, is a sedative and hypnotic drug and reported to possess anticonvulsant activity.

Recently, several scientists elucidated that quinazoline system possess variable sites at positions 2 and 3 which can be suitably modified by the introduction of different heterocyclic moieties to yield the potential anticonvulsant agents [3].

Incorporation of fluorine atoms or CF_3 group to heterocycles is known to influencing the biological activity [4]. Fluorinated quinazoline has been focused the attraction of pharmacologist and chemists during last several years due to wide variety of activity possess by them [5]. Number of patents mention the utility of fluorinated quinazolines as important antifungal [6], herbicidal [7], pesticidal [8], CNS depressant [9] and AMPA inhibitors [10] etc. Thus, their synthesis has been of great interest in the elaboration of biologically active heterocyclic compounds.

Microwave induced rate enhancement of various reactions becoming popular with organic chemists [11]. However, recently, more interest has been focussed on ''dry media'' synthesis and particularly on solvent-free procedure using various mineral oxides [12] and solvent-less reactions with neat reactants in the absence of a catalyst or solid support [13]. Recently, the diversity generating potential of multi-component reactions (MCR's) has been recognized and their utility in preparing libraries to screen for functional molecules is well appreciated. Consequently, the design of novel MCR's is an important field of research [14].

Conventional synthesis of disubstituted quinazolin-4(3H)-ones involves two steps [15] i.e. (i) cyclodehydration of 2-benzamidobenzoic acid **I** with excess of acetic anhydride under anhydrous conditions and removal of excess of acetic anhydride under reduced pressure to give benzoxazin-4-one **II** (ii) refluxing the **II** with amines in glacial acetic

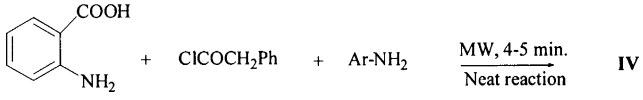
acid/pyridine [16]. The products were obtained in moderate yield and require 10–12 h refluxing.

The synthesis of quinazolin-4(3H)-one core nucleus under microwaves is reported involving the reaction of anthranilic acid with formamide [17]. But to the best of our knowledge, no report is available in the literature for fluorinated disubstituted quinazolines involving multi-component reaction for the synthesis of series of compound to make them available for bioactivity evaluation.

For the aforementioned reasons and in view of our general interest in the development of environmentally friendlier synthetic alternatives using microwaves [18], we studied extensively the synthesis of fluorine containing quinazolin-4(3H)-ones under microwave irradiation by various methods (Table 1) i.e., (A) using inorganic solid support montmorillonite KSF/acidic alumina (Scheme 1); (B) neat one-pot synthesis without using any dehydrating agent, solvent or support (Schemes 2 and 3). The best results obtained from neat synthesis (method B) have been reported.



Scheme 2.

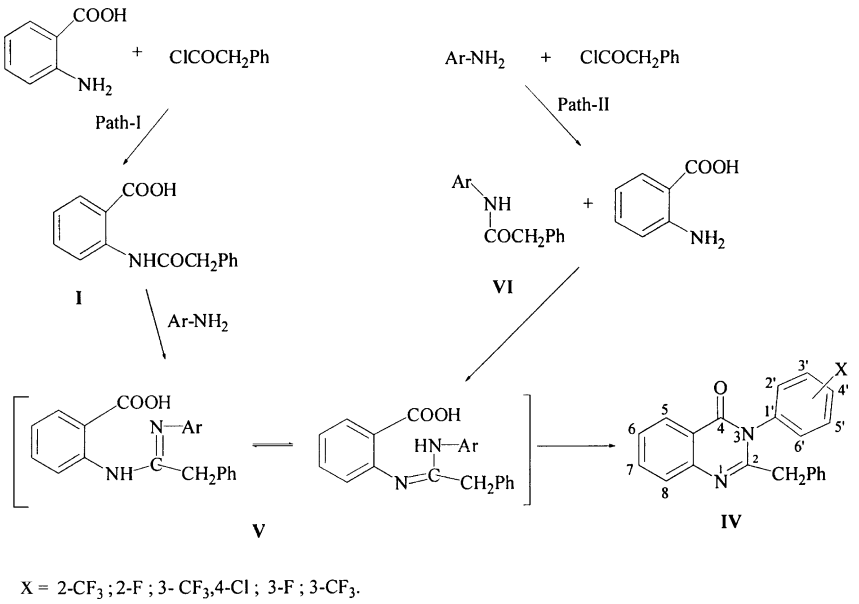
2. Results and discussion

In method A the intermediate benzoxazin-4-one **II** was synthesized "in situ" by the cyclodehydration of **I** with acetic anhydride using inorganic solid supports. The method is environmentally friendly, as acetic anhydride remains adsorbed over the solid support and there is no evaporation into the atmosphere.

The condensation reaction of **II** with *para*/*meta*/*ortho* substituted fluorinated anilines have been studied. *Meta*/*para* substituted anilines gave cyclized product quinazoline **IV**. While the *ortho* substituted anilines gave, an intermediate *O*-acylaminobenzanilide **III**, which in contrast to earlier report of Mishra et al. [15] where they reported the formation of cyclized quinazolones in case of *ortho* substituted anilines also.

Although, the solvent-free procedure using inorganic support under microwaves is an attractive ecofriendly methodology, but it requires appreciable amount of solvent for adsorption of reactants and elution of products.

Further, in view of our aim to synthesize a series of fluorinated 2,3-disubstituted quinazolones with pharmacophoric groups and to establish structure activity relationship in quinazolones, we have developed a 'green chemistry procedure' using neat multi-component reaction conditions, which aims at complete elimination of the solvent as well as solid support from the reaction. These no solvent reactions,



Scheme 3.

when coupled with microwave irradiation prove to be advantageous for environmental reasons as well, due to their uniforating effect and shorter reaction time.

Experimentally, anthranilic acid, phenyl acetyl chloride and corresponding substituted anilines (X = 2-CF_3; 2-F; 3-CF_3,4-Cl; 3-F; 3-CF_3) are admixed and irradiated inside the microwave oven. The formation of final product quinazolone **IV** can proceed via two pathways I & II (Scheme 3).

Path I involves first *N*-phenylacetylation of anthranilic acid and condensation of resultant 2-benzamidobenzoic acid **I** with the amines and then intramolecular amidation of the intermediate amidine **V** afforded the desired final product **IV**. While an another path **II** involves *N*-phenylacetylation of amines instead of anthranilic acid. The possibility of all routes are confirmed by isolation of intermediates in some cases or the reaction of 2-benzamidobenzoic acid **I** with 3-trifluoromethylaniline and the condensation of **VI** with anthranilic acid were conducted under microwave irradiation, the desired product **IVa** was obtained in few minutes. Thus, *N*-phenylacetylation step occurs very quickly. Attempts to use $PhCH_2COOH$ instead of $PhCH_2COCl$ were not successful.

In conclusion, we have introduced a simple one-pot multi-component cyclocondensation reaction for the synthesis of disubstituted quinazolin-4(3H)-ones without using any dehydrating agent, solvent or support. Reaction occurred in shorter time with easier work-up process and this method was applicable even when o-substituted anilines were used. While conventional method was failed to give **IV** in case of *O*-substituted anilines.

The formation of *O*-acyl aminobenzanilide **III** and quinazoline 4(3H)-ones **IV** have been confirmed on the basis of spectral studies. The IR spectra of **IIIa–b** (Table 2) showed characteristic absorption bands at 3360–3400 (NH), 1700–1680 (both C=O). The ^{1}H NMR spectra of **IIIa–b** showed broad peaks at δ 8.92 & 9.25 due to two NHCO protons (exchangeable with D_2O) and a singlet at δ 4.22–4.26 ppm due to $COCH_2Ph$ protons. ^{13}C NMR spectrum of **IIIa** also showed the presence of two carbonyl signals at δ169.9 and 169.2 ppm. The remaining signals were obtained at δ 140.8, 133.9, 133.6, 133.4, 130.7, 128.8, 128.3, 127.9, 126.4, 126.3, 125.5, 125.3, 121.8, 120.1, 119.2, (aromatic and CF_3 carbon) ($CO–CH_2$) 45.0 ppm.

IR spectra of quinazolones **IVa–f** showed the only one carbonyl absorption band at 1695–1700 and 1605–1610 (C=N) cm^{-1} confirms the ring closure in all compounds. It was further confirmed on the basis of ^{13}C NMR spectrum of **IVd** which showed only one signal at δ 169.7 (C=O) ppm along with other peaks at 155.4 (C=N), 139.5, 138.6, 137.5, 135.8, 131.3, 130.9, 129.3, 128.6, 127.3, 126.4, 125.6, 123.3, 122.0, 120.7, 119.5 (aromatic and CF_3 carbon) and (CH_2Ph) 24.1 ppm. Further, the disappearance of NH peaks in **IVa–f** peaks at (δ 8.92 and 9.25 ppm) showed the formation of quinazolones **IV**. The presence of fluorine attached to phenyl ring has been confirmed by ^{19}F NMR. The detailed spectral data of compound **IIIa–b** and **IVa–f**

are given in Table 3. In the mass spectrum of representative compounds the molecular ion peak at *m/z* 398 and 380 (100%) was corresponding to the molecular weight of compounds **IIIa** and **IVd**, respectively.

2.1. Evaluation of anti-fungal activity

The synthesized compounds were screened for antifungal activity against three pathogenic fungi, namely *Rhizoctonia solani*, causing root rot of okra, *Fusarium oxysporum*, causing wilt of mustard and *Colletotrichum capsici* causing leaf spot and fruit rot of chilli. It was done by two methods.

2.2. Poison plate technique [19]

The compounds synthesized were dissolved in acetone and compounds were prepared in 1000 and 500 ppm concentrations. Potato-dextrose-agar medium was prepared in flasks and sterilized. To this medium, a requisite quantity of solution was added and then the medium was poured into petri plates in three replication. A culture of test fungus was grown on PDA for 6–7 days. Small disc (4 mm) of fungus culture was cut with a sterile corkborer and transferred asceptically, upside-down in the center of petridishes containing the medium and fungicides. Plates were incubated at 25 ± 1 °C for 6 days. Colony diameter were measured and data was statistically analysed (Table 4).

2.3. Pot trial method [20]

White seeded sorghum grains were soaked in water for about 12 h, 160 g of the soaked kernels were placed in 500 ml flasks and 20 ml of water was added to each. The material was autoclaved twice on successive days before inoculation. After sterilization, fungus bits were inoculated in each flask and flasks were kept for 10 days at 25–27 °C.

Check with inoculum	12.00	4.00
Check without inoculum	95.00	90.00

DAS: Days after sowing.

100 seeds of okra were taken for one treatment of each compound. Inoculum was added @ 2 g/kg of soil, 3 days prior to sowing. Sowing was done after 3 days and germination data were recorded after 7, 15, 25 days of sowing. Suitable checks were maintained and the data was statistically analysed (Table 5). 'Baynate' and 'Thiram', standard fungicides as seed dressers to control this disease. 'Baynate' was found best in reducing the plant mortality.

3. Experimental

Melting points were determined in open glass capillary and were uncorrected. IR spectra were recorded on a Perkin-Elmer (model-577) in KBr pellets. ^{1}H NMR and ^{13}C NMR were recorded on Jeol model FX 90Q and Bruker-DRX-300 using $CDC1_3$ as solvent and TMS as internal reference at 89.55 and 75.47 MH_Z, respectively. ^{19}F NMR was recorded on Jeol model FX 90Q at 84.25 MHz, using $CDCl_3$ as solvent and or hexafluorobezene as external reference. Mass spectrum of representative compound was recorded on Kratos 50 mass spectrometer at 70 eV. Purity of all compounds were checked by TLC using silica gel 'G' coated glass plates and benzene-ethylacetate (8:2) as eluent. The microwave-induced reactions were carried out in BMO-700T modified domestic oven fitted with a condenser and a magnetic stirrer. Montmorillonite KSF and acidic alumina were Aldrich product and used as received. 2-benzamidobenzoic acid has been synthesized by literature method [21].

2-Phenylmethyl-3-(3-trifluoromethylphenyl)-quinazolin-4(3H)-one **IVa** was prepared by three different procedures under microwave irradiation.

3.1. Method A; Using inorganic solid supports (Scheme 1)

A mixture of 2-benzamidobenzoic acid **I** (2 mmol) and acetic anhydride (2.5 mmol) was adsorbed on acidic alumina/montmorillonite KSF (2 g), mixed thoroughly and irradiated inside the microwave oven at 640 W until the completion of reaction (TLC). After completion of reaction the 3-trifluoromethylaniline (2 mmol) was added to the reaction mixture and irradiated for appropriate time (Table 1). The product was extracted into ethanol and the excess solvent was evaporated on a roto-evaporator to give compound, which was purified by methanol and identified as **IVa**.

From the comparative results, it has been observed that the montmorillonite KSF is the best solid support as compared to acidic alumina (Table 1). The remaining compounds **IVb–c** and **IVf** (in case of *meta*/*para* substituted anilines) and **IIIa–b** (in case of *ortho* substituted anilines) were similarly prepared by using montmorillonite KSF.

3.2. Method-B; Neat-three-component cyclocondensation (Scheme 2)

An equimolar mixture of anthranilic acid (2 mmol), phenyl acetyl chloride (2 mmol) and 3-trifluoromethylaniline (2 mmol) contained in a Erlenmeyer flask fitted with condensor was placed in the microwave oven and irradiated for 5 min (TLC) at 640 W. The reaction mixture was cooled at room temperature to give solid mass which was crystallized from ethanol.

3.3. Method-C; Alternative procedure for preparation of IVa (Scheme 3)

A mixture of I (2 mmol) and 3-triflouromethyl aniline (2 mmol) was irradiated for 4 min (TLC) at 640 W. After

[a] Measured immediately after the reaction using a glass thermometer. Method A: using inorganic solid support; method B: neat one-pot synthesis. All compounds gave satisfactory elemental analysis (C, H and N) within ± .25% of theoretical value.

cooling, the resultant residue was crystallized from methanol yielding 91% of **IVa** (path I).

In order to verify the viability of path II under the above conditions, a mixture of phenyl acetyl anilide **VI** (2 m mol) and anthranilic acid (2 m mole) was irradiated (5 min, TLC). The resultant residue was crystallized from ethanol to give **IVa** yield = 90%.

The identity of compounds synthesized by various method was established by their mixed mp, IR and ^{1}H NMR spectral studies.

All compounds **IVb–f** listed in Table 6 were similarly synthesized by neat three-component method comparatively in high yield and reduced time.
