**ARTICLE HISTORY** Received 14 June 2020; Accepted 30 September 2020

A great deal of attention has been paid to developing methods for heterogenizing homogeneous catalysts in order to combine the advantages of both homogeneous and heterogeneous catalysis.<sup>1</sup> Among these methods, the binding of catalysts to organic polymer solids<sup>2</sup> or inorganic solids<sup>3</sup> is widely used. Although the heterogenized catalysts can be recycled and easily separated from the reaction mixtures, they are significantly less reactive and selective than their homogeneous counterparts. For this reason, there is a need to find new methods and strategies in order to overcome these limitations.

Graphene oxide (GO) and functionalized GOs are suitable for achieving this purpose. GO has a large amount of functional groups on its basal plane, and these allow for the modification of GO for further applications.<sup>4–6</sup> The large surface area and functional groups act as active sites. GO is a suspension in pure water but generally aggregates in salt solutions or in biological solutions.<sup>7</sup> To overcome this problem and also to permit easy separation by an external magnet, magnetic nanoparticles have been used. Magnetic nanoparticles (MNPs) such as magnetite ( $\text{Fe}_3\text{O}_4$ ) are of much current interest because of their magnetic and electrical properties, high specific surface area, unique catalytic powers and wide applications.<sup>8–10</sup>

Dendrimers are a comparatively new class of polymeric materials. They are highly branched, monodisperse macromolecules. The structure of these materials has a great impact on their physical and chemical properties. As a result of their unique characteristics, including enormous surface areas in relation to volume, the presence of internal cavities and the possibility of encapsulating guest molecules, dendrimers are suitable for a wide range of biomedical and industrial uses. For example, polyamidoamine (PAMAM), has been beneficially applied.<sup>11–14</sup>

We now describe a useful synthetic organic method based on combining the features of magnetic nanoparticles, GO and dendrimers. The objective of this strategy is to homogenize a heterogeneous catalyst. Thus we sought to: (i) use magnetic nanoparticles to minimize the support for the immobilization of the catalyst, while at the same time keeping it easily separable; and (ii) use the dendrimerization process to produce organic arms on the support. The latter action will enhance the compatibility of the material with the medium, allow it to mimic real homogeneous catalysts and promote our

<sup>a</sup>Reaction conditions: benzaldehyde (1 mmol) and malononitrile (1.2 mmol).

<sup>b</sup>This reaction was carried out in the absence of Fe<sub>3</sub>O<sub>4</sub>@GO@PAMAM (G<sub>2</sub>).

<sup>c</sup>No product **3a** observed.

**Scheme 1.** Synthesis of benzylidenemalononitrile derivatives catalyzed by Fe<sub>3</sub>O<sub>4</sub>@GO@PAMAM (G<sub>2</sub>).

synthetic purpose. We thus grew a PAMAM dendron on nanomagnetite Fe<sub>3</sub>O<sub>4</sub>@GO. The preparation of the Fe<sub>3</sub>O<sub>4</sub>@GO@PAMAM (G<sub>2</sub>) was accomplished according to a procedure described in the literature.<sup>15</sup>

The Knoevenagel condensation of aldehydes with compounds containing activated methylene groups is an important reaction for C=C bond formation in organic compounds. Because of its simplicity, economy and efficiency, this process is frequently used,<sup>16-21</sup> and we may note the use of numerous catalysts, including rare-earth (RE) exchanged NaY zeolite [RE(72%)NaY],<sup>22</sup> cetyltrimethyl ammonium bromide (CTMAB),<sup>23</sup> MgO/ZrO<sub>2</sub>,<sup>24</sup> Zn<sup>2+</sup> exchanged Hß (Znß),<sup>25</sup> polyvinyl chloride supported tetraethylenepentamine (PVC-TEPA),<sup>26</sup> Na<sub>2</sub>S/Al<sub>2</sub>O<sub>3</sub>,<sup>27</sup> magnesium fluoride,<sup>28</sup> Ni-SiO<sub>2</sub>,<sup>29</sup> ceria-zirconia (C/Z-30/70),<sup>30</sup> La<sub>2</sub>O<sub>3</sub>-MgO/KOH,<sup>31</sup> guanidine supported on magnetic nanoparticles Fe<sub>3</sub>O<sub>4</sub> (Fe<sub>3</sub>O<sub>4</sub>@guanidine),<sup>32</sup> BEA or TS-1 or CuBTC or FeBTC,<sup>33</sup> gallium chloride (GaCl<sub>3</sub>),<sup>34</sup> polyvinyl amine coated Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub> (Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub>-PVAm),<sup>35</sup> Fe<sub>3</sub>O<sub>4</sub>@UiO-66-NH<sub>2</sub>,<sup>36</sup> N-(3-trimethoxysilylpropyl)diethylenetriamine) coated (Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub>-3N),<sup>37</sup> Fe<sub>3</sub>O<sub>4</sub>@P4VP@ZIF-8,<sup>38</sup> magnetic Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub>@Ni-Zn-Fe layered double hydroxide (LDH) (Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub>@Ni-Zn-Fe LDH),<sup>39</sup> and fiber (PAN<sub>P</sub>F-3).<sup>40</sup>

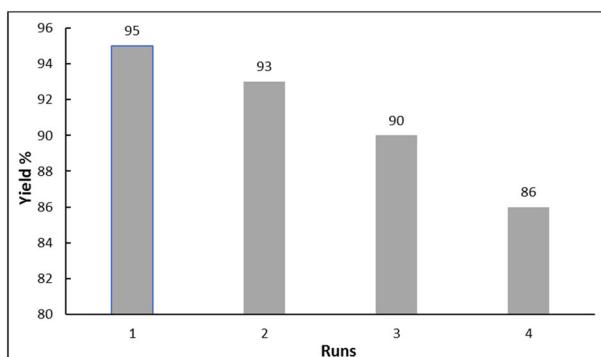

In furtherance of our studies of organic reactions in the presence of benign heterogeneous and homogeneous catalysts,<sup>41-50</sup> we now demonstrate the preparation of benzylidenemalononitrile (BMN) derivatives by Knoevenagel condensation of benzaldehydes (1 mmol) and malononitrile (1.2 mmol) using [Fe<sub>3</sub>O<sub>4</sub>@GO@PAMAM (G<sub>2</sub>)] as catalyst (Scheme 1).

To define the best conditions for this reaction, we optimized the type and amount of catalyst, temperature and solvent. Our study started by using benzaldehyde (1 mmol) and malononitrile (1.2 mmol) in a model reaction. Our results on optimization are shown in **Table 1**. The best results are represented by Entry 1, when the model reaction was carried out in the presence of  $\text{Fe}_3\text{O}_4@\text{GO}@\text{PAMAM}$  ( $\text{G}_2$ ) (0.008 g) under solvent-free conditions at 60 °C.

To probe the generality of this reaction we reacted malononitrile with ten aryl aldehydes substituted with both electron-withdrawing and electron-donating groups, including aldehydes with *ortho* substituents. The experiments were repeated three times for

**Figure 1.** Reusability of  $\text{Fe}_3\text{O}_4@\text{GO}@ \text{PAMAM} (\text{G}_2)$ .

each aldehyde and the average yields are reported in **Table 2**. The products were formed in high to excellent yields (see Experimental section; mean yield 88%).

The recyclability of the  $\text{Fe}_3\text{O}_4@\text{GO}@ \text{PAMAM} (\text{G}_2)$  was checked in the model reaction under optimized conditions. After completing the reaction, 1 mL ethanol was added to the reaction mixture and then the catalyst was easily separated using an external magnet.  $\text{Fe}_3\text{O}_4@\text{GO}@ \text{PAMAM} (\text{G}_2)$  was reused in the model reaction after washing with acetone and deionized water and drying. As shown in **Figure 1**, the nanocatalyst could be reused in four reaction runs before considerable loss in activity was observed.

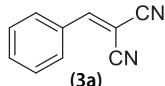

**Table 3** shows the efficiency of the present procedure for the synthesis of 2-benzylidene malononitrile (**3a**), compared with previously reported procedures in the literature. The data suggest that  $\text{Fe}_3\text{O}_4@\text{GO}@ \text{PAMAM} (\text{G}_2)$  stands among the best catalysts and has the desirable attributes of high yield, short reaction time and the avoidance of solvents.

In conclusion, our work illustrates the advantages of heterogenizing homogeneous catalysts in order to improve synthetic organic preparations. The efficiency of  $\text{Fe}_3\text{O}_4@\text{GO}@ \text{PAMAM} (\text{G}_2)$  as a reusable and highly effective catalyst was illustrated for the synthesis of benzylidenemalononitrile derivatives through the Knoevenagel reaction. Over-all, this synthetic approach provides excellent yields and short reaction times. Among the green characteristics of this method are low waste generation, the avoidance of solvent, simple work-up, easy separation and reusability of catalyst. We hope that our catalyst can be applied for the promotion of a wide range of Knoevenagel reactions and other related reactions.

## Experimental section

All reagents were obtained from commercial sources. Melting points were determined on an Electrothermal 9200 apparatus and are uncorrected. IR spectra were recorded at room temperature on a Shimadzu 435-U-04 spectrophotometer using KBr disks and are reported in  $\text{cm}^{-1}$ . A Bruker DRX-400 Avance spectrometer was used for recording  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra at 400 MHz and 100 MHz in  $\text{CDCl}_3$  or  $\text{DMSO-d}_6$  using tetramethylsilane as an internal standard. First order aromatic couplings were within the expected range and are not enumerated. The catalyst was prepared according to the method previously described.<sup>15</sup>

**General procedure for synthesis of benzylidenemalononitrile derivatives (**3a-j**) catalyzed by  $\text{Fe}_3\text{O}_4@\text{GO}@\text{PAMAM (G}_2\text{)}$**

$\text{Fe}_3\text{O}_4@\text{GO}@\text{PAMAM (G}_2\text{)}$  (0.008 g) was added to a mixture of the benzaldehyde (1 mmol) and malononitrile (1.2 mmol). The mixture was heated at 60 °C on an oil bath under solvent-free conditions for the appropriate time (Table 2). The progress of reaction was monitored by TLC (silica gel; n-hexane:ethyl acetate, 4:1). After completion of the reaction, 1 mL ethanol was added to the mixture and then the nanocatalyst was easily separated using an external magnet. The resulting mixture was poured into crushed ice to precipitate the product. The product was filtered off and was recrystallized from ethanol (96%) to get the respective pure 2-benzylidenemalononitrile derivatives (**3a-j**). All of the compounds in this study were known and were identified by matching their melting points with the literature values cited in Table 2. For the sake of completeness, representative IR, <sup>1</sup>H-NMR and <sup>13</sup>C-NMR are provided below for compounds **3d** and **3h**.

**2-(3-Methoxybenzylidene)malononitrile (**3d**)**

IR (KBr) 3039, 2217, 1575, 1470, 1249, 756, 613 cm<sup>-1</sup>; <sup>1</sup>H-NMR (DMSO-d<sub>6</sub>, 400 MHz) δ: 8.47 (s, 1H, CH), 7.95-7.97 (d, 1H, CH, aromatic), 7.66-7.70 (d, 1H, CH aromatic), 7.13-7.24 (m, 2H, 2CH aromatic), 3.906 (s, 3H, OCH<sub>3</sub>); <sup>13</sup>C-NMR (DMSO-d<sub>6</sub>, 100 MHz) δ: 159.10, 156.50, 136.99, 129.33, 120.39, 120.35, 114.88, 113.73, 112.89, 81.99, 56.52.
