Received (in Cambridge, UK) 30th March 1999, Accepted 7th May 1999

Chiral boron-bridged *ansa*-type zirconocenes can be prepared in a few simple steps; various donor molecules such as Et₂O, THF or PMe₃ undergo complexation at boron leading to catalysts having vastly different catalytic properties in Ziegler–Natta polymerization of propene; the PMe₃-containing catalyst is the most active and stereoselective (96% isotacticity).

The nature of substituents and the substitution pattern of titanocenes and zirconocenes are known to exert a pronounced influence on their activity and selectivity as catalysts in Ziegler–Natta polymerization.¹ Recently, several zirconocenes borylated at the Cp-moiety have been prepared and tested as catalysts.^{2,3} None of them showed activity in the polymerization of propene, and some even failed to polymerize ethene,³ possibly due to decomposition caused by the co-catalyst methylalumoxane (MAO) which is generally required as an activator. Here, we describe the synthesis of donor-coordinated *ansa*-type zirconocenes **1** and their use as catalysts in the

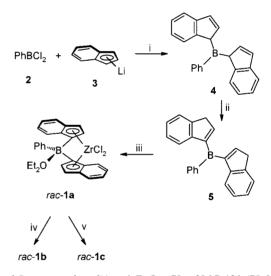

production of polypropene (PP). Significantly, it turns out that the nature of the donor ligand L determines the activity and stereoselectivity of the catalytic system, *i.e.* it can be used as a handle to control the polymerization.

The starting point for the synthesis of zirconocenes **1** was bis(1*H*-inden-1-yl)phenylborane **4**, readily accessible as a 1:1 mixture of *rac*- and *meso*-stereoisomers by the reaction of dichlorophenylborane **2** with indenyllithium **3** (Scheme 1). Although it was possible to convert **4** into the corresponding dianion by treatment with lithium bis(trimethylsilyl)amide (LiHMDS),⁴ at least 20% of indenyllithium **3** was formed as an undesired side-product. This problem was solved by first isomerizing **4** into the thermodynamically more stable compound **5** in 95% yield by the action of catalytic amounts of PPrⁱ₃ and then effecting double deprotonation. Upon reacting ZrCl₄ with the intermediate dianion, a 1:1 mixture of *rac*-**1a** and *meso*-**1a** as well as non-identified side-products were formed.

Following removal of solid components, the solution was cooled to -20 °C, from which diastereomerically pure *rac*-**1a** crystallized as an orange–red solid in 12% yield. It was unambiguously characterized by ¹H, ¹¹B and ¹³C NMR spectroscopy. Treatment of *rac*-**1a** with a solvent mixture of THF and CH₂Cl₂ led to the formation of *rac*-**1b** whereas the reaction with PMe₃ in toluene afforded adduct *rac*-**1c**. In both cases it was possible to obtain crystals suitable for an X-ray structural analysis (Fig. 1).† It should be mentioned that a different boron-bridged zirconocene has been described previously, but it was not possible to obtain crystals for an X-ray structural analysis, nor did it show activity towards ethene polymerization.³ PMe₃ has been used to form adducts with other borylated metallocenes.^{2c} The present *C*₁-symmetric

compounds are structurally similar. In the case of *rac*-**1b** the angle between zirconium and the center of the two fivemembered rings is $122.3(8)^{\circ}$ (mean), which lies between that of the known Me₂C-bridged bis(indenyl)dichlorozirconium $(118.2^{\circ})^{5}$ and that of the Me₂Si-bridged analog $(127.8^{\circ}).^{6}$ For *rac*-**1c** this angle was found to be $121.5(7)^{\circ}$, similar to that in *rac*-**1b**. Nevertheless, the Zr···B–O angle in *rac*-**1b** [120.4(6)°] is significantly smaller than the Zr···B–P angle in *rac*-**1c** [131.3(2)°].

In order to test the complexes in olefin polymerization, activation by treatment with MAO in toluene for 5 min was performed in all cases. Although compound *rac*-**1a** was found to be a fairly active catalyst (200–2600 kg PE mol[Zr]⁻¹ h⁻¹)

Scheme 1 *Reagents and conditions*: i, Et₂O, -70 to 20 °C, 12 h (75–85%); ii, PPri₃ (2 mol%), Et₂O, 20 °C, 16 h (85%); iii, (*a*) LiHMDS (2.05 equiv.), Et₂O, -70 to 20 °C, 10 h; (*b*) ZrCl₄ (1 equiv.), toluene–Et₂O, -70 to 20 °C, 12 h; iv, THF–CH₂Cl₂ (1:1); v, PMe₃ (7 equiv.), toluene, -70 to 20 °C (21%).

Table 1 Polymerization of propene with rac-1c in toluene as solvent and MAO as activator^a

T/°C	Al : Zr	Productivity/kg PP mol[Zr] ⁻¹ h ⁻¹	$10^{-3} M_{\rm w}/{\rm g \ mol^{-1}}$	Tacticity (% mmmm- pentades)
20	1000	326	315	96
40	220	783	161	93
40	1000	1052	129	90
40	5000	1232	97	93
60	1000	174	62	85

for ethene polymerization producing high molecular weight polymer ($M_w \approx 700000$ g mol⁻¹ as determined by GPC), this complex turned out to be a rather poor catalyst for the polymerization of propene. For example, using a Al/Zr ratio of 1000, activities of only 10–75 kg PP mol[Zr]⁻¹ h⁻¹ were observed at room temperature with the production of atactic oily PP ($M_w \approx 20000$ g mol⁻¹). In contrast, the phosphine adduct *rac*-1c displayed remarkably high activity and stereoselectivity (Table 1). ¹³C NMR spectra of typical PP samples obtained at various polymerization temperatures demonstrate high degrees of isotacticity, *e.g.* 96% isotacticity at room temperature.

Thus, complex *rac*-1c is the first boron-bridged zirconocene which catalyzes the polymerization of propene. It competes well with other *ansa*-type zirconocenes, especially with respect to isotacticity and molecular weight.^{5,6} Since the ether analog *rac*-1a is a poor catalyst, it is obvious that the nature of the donor ligand at boron is crucial. A possible explanation is that for *rac*-1a excess MAO induces decomplexation of the donor ligand, thereby initiating the decomposition of the *ansa*-metallocene, whereas for *rac*-1c the donor ligand PMe₃ remains bonded to boron throughout the polymerization. Whatever the exact explanation may be, it is clear that the use of PMe₃ provides a handle to control activity and tacticity. It remains to be seen whether other phosphines or different donor ligands induce similar effects.
