Abstract

Calonyctin A2, a tetrasaccharidic glycolipid having a 22-membered macrolidic structure, has been synthesized by the assembly of three 6-deoxygenated thioglycoside intermediates. The short-step synthesis was achieved by preparation of the most complicated b–c disaccharide unit from phenyl 2,2':4,6:4',6'-tri-*O*-benzylidene-1-thio- β -D-laminaribioside without any glycosidation reaction and by regioselective macrolactonization. © 2000 Elsevier Science Ltd. All rights reserved.

Keywords: carbohydrates; glycolipids; calonyctin A; glycosides; macrolides; thioglycosides.

Calonyctin extracted from the leaves of Yue-Guang-Hua (*Calonyction aculeatum* L. House) is a plant growth regulator, which promotes the tuber production of sweet potato and increases the crop yields of beans and wheat.¹ It is a mixture of homologous glycolipids consisting of a common deoxygenated tetrasaccharide residue and 11-hydroxy fatty acids,² which are named calonyctin A1 (**1**) and A2 (**2**), respectively (Fig. 1).³ Furthermore, one of the sugar hydroxyl groups is acylated with (2*R*,3*R*)-3-hydroxy-2-methylbutyric acid. The most remarkable feature of their structure is that they have a 22-membered macrolide ring. The absolute configuration of the aglycon moiety was determined as *S* by Schmidt's synthesis of **1** from a racemic fatty acid.⁴ In this communication, we describe an expeditious synthesis of calonyctin A2 (**2**) using laminaribiose as the starting material. On the basis of our studies on the chemical modification of laminaribiose,⁵ we envisioned that the readily accessible tri-*O*-benzylidene derivative **3** could be used as a synthon for the most complicated disaccharide unit (Qui-b and Qui-c) of **2**. Compound **3** was converted into a crucial disaccharide donor, phenyl 3'-*O*-allyl-2,2'-di-*O*-benzoyl-4,4'-di-*O*-benzyl-6,6'-dideoxy-1-thio- β -D-laminaribioside **8**, which had to be coupled with a monosaccharide intermediate **17** and a L-rhamnosyl donor **21**. Furthermore, an optically active 11(*S*)-hydroxymyristic acid derivative **14** could be prepared from the known (*S*)- γ -tosyloxymethyl- γ -butyrolactone in an enantioselective manner.

Fig. 1.

The synthetic route of the disaccharide donor **8** is illustrated in Scheme 1. Thus, **3** was allylated at the unprotected hydroxyl group to give the fully protected disaccharide **4**. Upon treatment of **4** with PPTS in CHCl_3 –MeOH at room temperature, the most labile *O*-benzylidene group with an eight-membered ring underwent selective cleavage, to give the 2,2'-diol **5** in 79% yield based on consumed **4**. The following reductive cleavage of the benzylidene group in **5** was one of the most difficult steps in the present synthesis, and this was overcome by applying Kusumoto's reagent system.⁷ Treatment of **5** with $\text{BH}_3 \cdot \text{Me}_2\text{NH} \cdot \text{BF}_3 \cdot \text{OEt}_2$ in CH_2Cl_2 gave the desired 2,6,2',6'-tetraol **6** in 77% yield without any affection on the other protecting groups.⁸ The conventional reduction of **5**, or its 2,2'-di-*O*-acetyl derivative with $\text{BH}_3 \cdot \text{Me}_3\text{N} \cdot \text{AlCl}_3$ ⁹ or DAIBAL-H,¹⁰ Super-Hydride[®], failed due to poor regioselectivity and undesirable cleavage of the protecting group. Subsequently, **6** underwent selective esterification in a one-pot manner with TsCl and then with excess BzCl, giving the labile 2,2'-di-*O*-benzoyl-6,6'-di-*O*-tosyl derivative **7**. Without purification, **7** was reduced with NaBH_4 in DMF at 70°C into the dideoxy derivative **8** in an overall yield of 47% from **6**.

Scheme 1. Reagents and conditions: (a) AllylBr, NaH, DMF; (b) PPTS, MeOH/ CHCl_3 ; (c) $\text{BF}_3 \cdot \text{OEt}_2$, $\text{Me}_2\text{NH} \cdot \text{BH}_3$, CH_2Cl_2 , under N_2 ; (d) TsCl, pyridine, then BzCl; (e) NaBH_4 , DMF, 70°C

For the synthesis of the aglycon moiety of **2**, the optically active pentanetriol¹¹ **9** derived from L-glutamic acid was subjected to selective silylation and subsequent basic treatment with *tert*-BuOK in THF to give the epoxide **10** (Scheme 2). Treatment of **10** in THF with 9-(benzyloxy)nonyl magnesium bromide in the presence of CuI and subsequent benzylation gave **11**⁶ in an overall yield of 72%. A three-step reaction involving de-*O*-silylation with Bu_4NF , bromination with CBr_4 – PPh_3 ,¹² and reduction with Bu_3SnH –AIBN was carried out to give **12**.⁶ Treatment of **12** with methanolic sodium methoxide followed by Birch reduction gave the tetradecan-1,11-diol⁶ **13**. Finally, a primary hydroxyl group of **13** was subjected to two-step oxidation¹³ with TEMPO and subsequently with sodium chlorite to give 11(*S*)-hydroxymyristic acid, which was isolated and characterized as the methyl ester **14**.⁶ In order

to construct the target compound **2**, two other intermediates, phenyl 2-*O*-acetyl-3,4-di-*O*-benzyl-6-*O*-mesyl-1-thio- β -D-glucopyranoside¹⁴ **15** and phenyl 2,3,4-tri-*O*-benzyl-1-thio- α -L-rhamnopyranoside¹⁵ **21**, were prepared.

Scheme 2. Reagents and conditions: (a) TBDPSCl, pyridine/CH₂Cl₂, then *tert*-BuOK, THF; (b) 9-(benzyloxy)nonyl magnesium bromide, CuI, THF, 0°C; BzCl, pyridine; (c) *n*-Bu₄NF, THF; CBr₄, Ph₃P, DMF, then Bu₃SnH, AIBN, toluene, 80°C; (d) NaOMe, MeOH, 70°C, then liq. NH₃, Na, -80°C; (e) TEMPO, TBACl, NCS, CH₂Cl₂/H₂O, pH 8.6; NaClO₂, NaH₂PO₄, *tert*-BuOH, 2-methyl-2-butene/H₂O, then CH₂N₂, Et₂O; (f) thioglycoside¹⁴ **15**, NIS-TfOH, CH₂Cl₂, MS 4 Å, -20°C, then NaOMe, MeOH; (g) NaBH₄, DMF, 70°C; (h) **8**, NIS-TfOH, CH₂Cl₂, MS 4 Å, -20°C; (i) 2 M KOH, MeOH, 40°C; (j) Cl₃C₆H₂COCl, Et₃N, DMAP, toluene; (k) thioglycoside¹⁵ **21**, NIS-TfOH, CH₂Cl₂, MS 4 Å, -20°C; (l) RhCl(PPh)₃, diazabicyclo[2,2,2]octane, EtOH, reflux; 2 M HCl, 45°C, then (2*R*,3*R*)-3-benzyloxy-2-methylbutyric acid, DMAP, WSC, CH₂Cl₂; (m) Pd/C, H₂, MeOH

Assembly of the four intermediates (**8**, **14**, **15** and **21**) were performed by iodonium activation of the thioglycosides. At first, **14** and the glucosyl donor **15** were treated with NIS-TfOH¹⁶ in CH₂Cl₂ at -20°C, and the β -glucoside **16** was isolated after de-*O*-acetylation. Reduction of the mesyloxy group in **16** with NaBH₄ in DMF gave the glycosyl acceptor⁶ **17**, which was coupled with **8** in a similar way to afford the trisaccharide⁶ **18** in 71% yield. After saponification with aqueous NaOH, the resulting carboxylic acid **19** was subjected to macrolactonization by a mixed anhydride procedure¹⁷ under high-dilution conditions in toluene (1.71×10^{-4} M). Although two possible hydroxyl groups are present at the 2b- and 2c-positions, the desired 22-membered macrolide⁶ **20** was obtained as a single product in 60% yield together with recovered starting material **19**. The structure of **20** was unambiguously corroborated by two-dimensional COSY and NOESY NMR spectroscopy. Similar glycosylation of **20** with the L-rhamnosyl donor **21** gave the tetrasaccharide⁶ **22** in 15% yield, which was not improved by use of another thiophilic reagent, MeOTf. The low yield was probably due to steric hindrance of the hydroxyl

group at the 2a-position. To synthesize the target compound, the allyl group in **22** was isomerized with Wilkinson's catalyst and the propenyl group was removed by acid hydrolysis. The resulting alcohol was esterified with (2*R*,3*R*)-3-benzyloxy-2-methylbutyric acid⁴ in the presence of water-soluble carbodiimide in CH₂Cl₂, giving the fully protected derivative **23** in 62% yield. Finally, removal of all benzyl groups in **23** by catalytic hydrogenolysis gave calonyctin A2 (**2**), of which the NMR spectra in pyridine-*d*₅ were consistent with those already reported.²
