Received 4 June 1998; accepted 15 June 1998

Abstract: A convergent and stereoselective synthesis of the C31-C46 side chain unit in the marine natural product phorboxazole A, which accommodates five asymmetric centres, three carbon-to-carbon double bonds and an oxane-hemiacetal unit, is described. © 1998 Elsevier Science Ltd. All rights reserved.

Phorboxazole A **1** is a unique marine natural product which has been isolated from the Indian Ocean sponge *Phorbas* sp.[1] The molecule exhibits profoundly potent cytostatic activity against human tumour cell lines and it has an unprecedented structure based on a macrolactone core, four oxane and two oxazole rings, and accommodates fifteen asymmetric centres and five *E*- and one *Z*- olefinic bonds. The pronounced biological activity of this novel structure has aroused considerable interest in its total synthesis.[2] In recent work we have disclosed a synthesis of the 2,6-*cis*-oxane unit **3** in phorboxazole A.[3] In this communication we present a concise synthesis of the C31-C46 side chain portion **2**[4] of the natural product which is appropriately functionalised for subsequent connection to the oxane unit **3** *via* an oxazole ring forming sequence.[5]

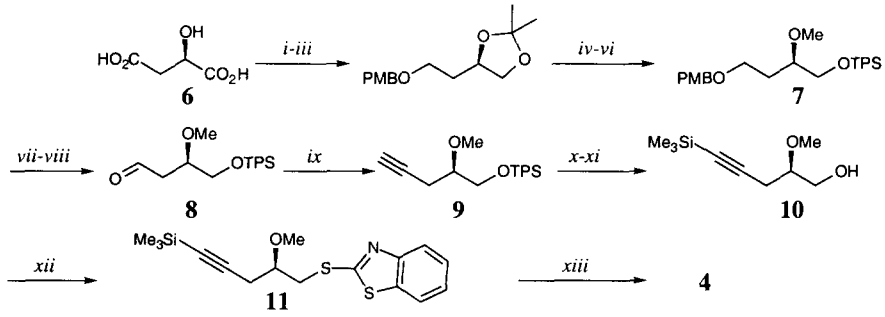
5

Our approach to the C31-C46 portion **2** in phorboxazole A was based on a convergent approach using an *E*-selective Julia benzothiazole sulfone olefination reaction[6] between the sulfone **4** and the α,β-unsaturated aldehyde **5** as a key step. Furthermore, we planned to synthesise the sulfone **4** and the aldehyde **5** from the chiral pool compounds *D*-malic acid **6** and *D*-xylose **12** respectively.

Thus, *D*-malic acid **6** was first converted into the differentially protected triol **7** using six straightforward steps in 43% overall yield as shown in Scheme 1.[7] Deprotection of the PMB ether group in **7**, using DDQ,[8] followed by oxidation of the resulting primary alcohol under Swern conditions next led to the

PII: S0040-4039(98)01258-1

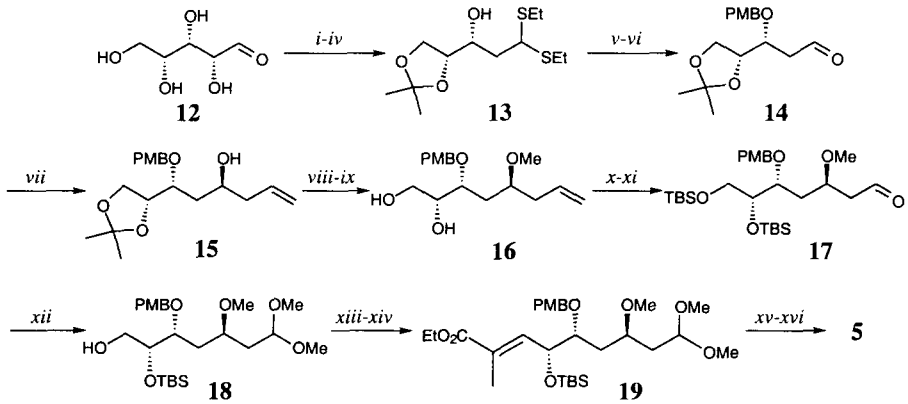
aldehyde **8** which was then converted into the terminal acetylene **9** using Seyferth's reagent.[9] The primary alcohol function in **9** was unmasked and the terminal acetylene residue was then protected as the corresponding trimethylsilane derivative **10**. Treatment of **10** with 2-mercaptobenzothiazole in the presence of Ph_3P - DEAD next gave the sulfide **11**,[6] which on oxidation using *m*-CPBA finally produced the benzothiazole sulfone intermediate **4** as a stable crystalline solid.[7]



Reagents: *i*, $BH_3.SMe_2$, $B(OEt)_3$; *ii*, Me_2CO, *p*TSA, $Cu(II)SO_4$, 77% (2 steps); *iii*, PMBCl, $KOBu^t$, NBu_4I; *iv*, *p*TSA, MeOH, 69% (2 steps); *v*, TBDPSCl, Et_3N, DMAP, 94%; *vi*, NaH, MeI, 87%; *vii*, DDQ, 95%; *viii*, $(COCl)_2$, DMSO, Et_3N, 90%; *ix*, $(MeO)_2PCHN_2$, $KOBu^t$, 75%; *x*, TBAF, 96%; *xi*, TMSCl, BuLi, 70%; *xii*, 2-mercaptobenzothiazole, PPh_3, DEAD, 94%; *xiii*, *m*-CPBA, $NaHCO_3$, 85%.

Scheme 1

The *E*-α,β-unsaturated aldehyde **5** required for coupling to the sulfone **4** was elaborated from *D*-xylose as outlined in Scheme 2. Thus, *D*-xylose **12** was first converted into the thioacetal **13** in four steps based on procedures described by Gray *et al.*[10] Protection of the alcohol group in **13** as its PMB ether followed by hydrolysis of the thioacetal next gave the aldehyde **14**. Treatment of the aldehyde **14** with (-)-β-allyl diisopinocampheylborane[11] followed by oxidation with H_2O_2 - NaOH led to the homoallylic alcohol **15** which on methylation and deprotection of the acetonide was then converted into the 1,2-diol **16**. After



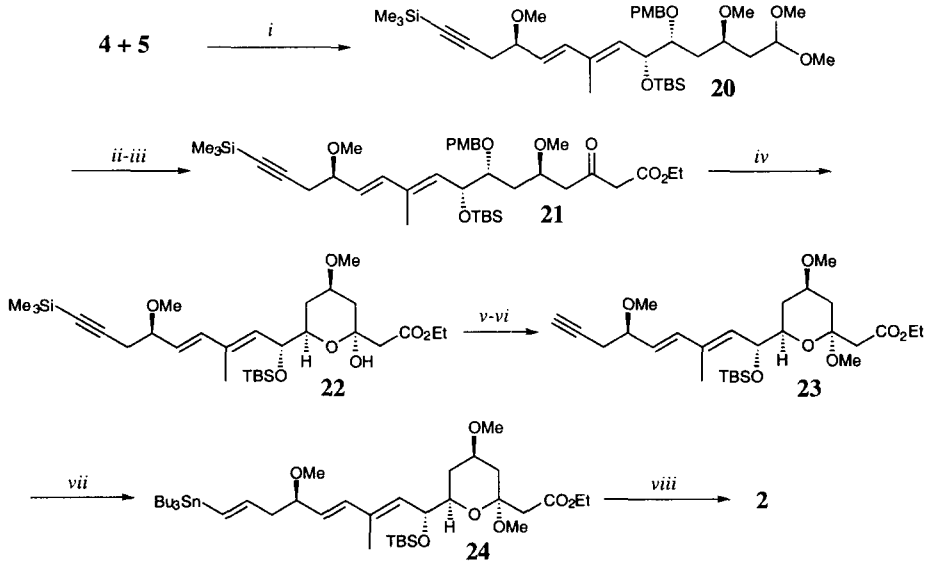
Reagents: *i*, EtSH, HCl, 65%; *ii*, Me_2CO, H_2SO_4, 90%; *iii*, $KOBu^t$, DMSO, 68%; *iv*, $LiAlH_4$, 92%; *v*, $KOBu^t$, PMBBr, 98%; *vi*, $Hg(ClO_4)_2$, $CaCO_3$, 91%; *vii*, a) (-)-β-allyl diisopinocampheylborane, b) H_2O_2, NaOH, 82%; *viii*, $KOBu^t$, MeI, 98%; *ix*, *p*TSA, MeOH, 88%; *x*, TBDMSOTf, Et_3N, 98%; *xi*, OsO_4, $NaIO_4$, 94% (2 steps); *xii*, CSA, MeOH, 89%; *xiii*, Dess-Martin periodinane, 93%; *xiv*, $CH_3C(PPh_3)CO_2Et$, 91%; *xv*, DIBAL, 89%; *xvi*, Dess-Martin periodinane, 94%.

Scheme 2

protection of **16** as the corresponding *bis*-TBS derivative, oxidative cleavage of the terminal double bond gave rise to the aldehyde **17**. Treatment of the aldehyde **17** with camphorsulfonic acid in methanol resulted in simultaneous acetal formation and deprotection of the primary alcohol leading to **18**.Oxidation of **18** with

Dess-Martin periodinane[12] followed by a Wittig reaction between the resulting aldehyde and $CH_3C(PPh_3)CO_2Et$ then led to the *E*-unsaturated ester **19**.[13] Finally, reduction of **19** using DIBAL and oxidation of the product alcohol with Dess-Martin periodinane gave the *E*-α,β-unsaturated aldehyde **5**.

Deprotonation of the sulfone **4** using NaHMDS in THF at -78°C in the presence of the *E*-unsaturated aldehyde **5** resulted in stereoselective formation of the *E,E*-diene **20** in a satisfying 74% yield.[13] Deprotection of the dimethyl acetal group in **20**, and treatment of the resulting aldehyde with ethyl diazoacetate next led to the β-keto ester **21**.[14] Removal of the PMB protecting group in **21** using DDQ in CH_2Cl_2[8] resulted in spontaneous cyclisation of the intermediate δ-hydroxy ketone producing a single diastereoisomer of the cyclic hemiacetal **22** in 90% yield. The synthesis of the target molecule **2** was then completed following protection of **22** as its methyl ether, deprotection of the terminal acetylene unit, hydrostannylation of **23** and treatment of the resulting vinylstannane with NBS in CH_3CN at 0°C. A significant amount of the p.m.r and c.m.r chemical shift and coupling data recorded for **2** matched, and could be superimposed on corresponding data for the C31-C46 side chain in natural phorboxazole A.[1]



Reagents: *i*, NaHMDS, -78°C, 74%; *ii*, Me_2BBr, -78°C, 95%; *iii*, EtO_2CCHN_2, $SnCl_2$, 75%; *iv*, DDQ, 90%; *v*, PPTS, MeOH, 50%; *vi*, $AgNO_3$, KCN, 75%; *vii*, Bu_3SnH, AIBN, C_6H_6, Δ; *viii*, NBS, 60% (2 steps).
