Palladium complexes incorporating ligands based on a 1,3,5,7-tetramethyl-2,4,8-trioxa-6-phosphaadamantanyl scaffold were used to catalyze the arylation of ethyl cyanoacetate, malononitrile, and various ketones. The products from these reactions can be elaborated to substituted β -arylethylamines and used in microwave-assisted Pictet–Spengler reactions. The protocol developed is suitable for the synthesis of libraries of substituted isoquinolines.

A number of methods have been described in the chemical literature suitable for the synthesis of substituted isoquinolines (1).¹ Among these, approaches that utilize the Pictet–Spengler² or Bischler–Napieralski³ reactions are among the most versatile and robust. Both these routes involve the derivatization of a β -arylethy-lamine (2) followed by cyclization and oxidation to give the isoquinoline ring system (shown retrosynthetically in Figure 1). We have previously described microwave-assisted variants of the Pictet–Spengler and Bischler–Napieralski reactions and used these protocols for the preparation of substituted isoquinoline libraries.⁴ During the course of these studies, it became apparent that access to suitably functionalized β -arylethylamines was

key to synthesizing isoquinolines substituted at the 3and 4-positions.

Compounds containing "active methylenes", such as ketones, aldehydes, esters, cyanoacetates, and malononitrile have been coupled with aryl halides using palladium catalysis.⁵ We became interested in the products from these reactions as they represent useful synthons of the β -ary-lethylamines required in the Bischler–Napieralski and Pictet–Spengler reactions. For example, Pd-catalyzed arylation of a nitrile possessing an α -methylene with an aryl halide **5** provides compound **3** that can be reduced to the

 β -arylethylamine 2 (where R'' = H). Alternatively, Pdcatalyzed arylation of a ketone provides compounds of the general type 4 that can undergo reductive amination to supply 2 and elaborated to give the desired isoquinolines 1. The present paper describes the use of palladium complexes incorporating ligands based on the 1.3.5.7-tetramethyl-2,4,8-trioxa-6-phosphaadamantane (PA) scaffold⁶ in the arvlation of cvanoacetates, malononitrile, and ketones along with the use of the compounds generated in the synthesis of substituted isoquinolines.

Initial efforts involved optimization of the reaction parameters (solvent, base, palladium source, and ligand) for the coupling between 3- and 4-iodoanisole and ethyl cvanoacetate. Screening (presented in Table 1) indicated that maximal yields were obtained when Pd₂(dba)₃·CHCl₃ was used as the palladium source and 1.3.5.7-tetramethyl-2,4,8-trioxa-6-iso-butyl-6-phosphaadamantane (PA-iBu) was employed as the ligand. NaH proved to be the best base while reactions carried out in THF provided the highest yields. Finally, 3 equiv of the nucleophile for each equivalent of aryl halide was determined to be the optimal stoichiometric ratio.

4-iodoanisole Pdodbas

or malononitrile. The results are presented in Table 2. It should be noted that the synthetic plan to isoquinolines involves the reduction of these nitriles to β -arylethylamines followed by cyclization. As the planned Bischler-Napieralski and Pictet-Spengler reactions involve electrophilic aromatic substitution, many of the cross-couplings presented in Table 2 involve electron-rich aryl halides. As expected, the yields for the aryl iodides were uniformly better than those of the analogous bromides. In addition, it was noted that reactions with aryl bromide were generally slower. Overall yields ranged from good to moderate. Finally, we noted that reproducibility with respect to product yields became an issue if oxygen was not strictly excluded from the reaction. This is likely due to the propensity of the PA-iBu ligand to undergo oxidation when dissolved in solvent.

Conditions for the reduction of the nitriles to β -arylethylamines were then examined (Figure 2). Ethyl 2-cyano-2-(3,4-dimethoxyphenyl)ethanoate (Table 2, entry 10) was used as our model substrate. Attempts at reduction using hydrogenation over Pd/C^7 resulted in numerous side products and incomplete reduction presumably due to catalyst poisoning. Hydrogenation using

Raney Ni⁸ was met with limited success with ethyl 3-amino-2-(3,4-dimethoxyphenyl)propanoate (7) isolated in 12% yield. Given the moderate yields associated with the cross-coupling of electron-rich aryl halides and the issues surrounding the nitrile reduction, we felt that this approach would be unsuitable for the preparation of isoquinoline libraries.

Figure 2. Reduction of ethyl 2-cyano-2-(3,4-dimethoxyphenyl)-ethanoate.

Our attention was then turned to the development of a protocol for the synthesis of β -arylethylamines *via* an α -ketone arylation/reductive amination sequence. We have previously described the use of the Pd/PA-Ph system for the effective α -ketone arylation of aryl halides.^{6a} These conditions were applied to provide the ketones shown in Table 3 (compounds of the general type **a**).

A number of reductive amination conditions were screened.⁹ Ultimately, we determined that the procedure described by Horiguchi and co-workers provided the best results.¹⁰ Treatment of the ketone with methanolic ammonia in the presense of titanium isopropoxide followed by addition of NaBH₄ generated primary amines (Table 3. compound b) in very good yields. While NaBH(OAc)₃ and NaBH₃(CN) were screened as reducing agents, it was found that NaBH₄ was far superior for these reaction conditions. It should also be noted that no attempt was made to separate the diastereomeric amines generated in the reaction. Rather, purification was carried out using reverse-phase preparative LC/MS with all fractions containing the correct mass for the product amine pooled together. Interestingly, the NMR of collected fractions showed the presense of a single species for entries 1b, 2b, and 3b while two diastereomers were clearly resolved for entry 4b. In all cases, the diagnostic signal for the newly installed hydrogen alpha to the amino group was clearly evident.

The β -arylethylamines thus produced could then be subjected to our previously developed microwave-assisted Pictet-Spengler/oxidation sequence. Treatment of the amine with 8 equiv of TFA in toluene was followed by microwave heating at 140 °C for 60 min. No attempts were made to separate or isolate the intermediate, diastereomeric tetrahydroisoquinolines. Rather, oxidation of the

crude tetrahydroisoquinoline mixture to the corresponding isoquinoline derivatives involved dehydrogenation using Pd/C in refluxing toluene followed by purification. Application of the Pictet–Spengler/oxidation sequence was applied to the parallel synthesis of a small collection of isoquinolines (presented in Table 4). The yields presented are based on the amount of amine used as a starting material and are fairly consistent across the variety of substrates employed.

Overall, the α -ketone arylation/reductive amination/microwave-assisted Pictet-Spengler/oxidation sequence developed has demonstrated itself to be a convenient method for the synthesis of small and moderate sized, substituted isoquinoline libraries.
