Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

Abstract (Word Style "BD Abstract"). The first synthesis and photophysical properties of a fluorecently-labeled camptothecin derivative namely camptothecin-FI (CPT-FI), an antitumoral agent

ACS Paragon Plus Environment

that targets topoisomerase I, are reported. The preparation of this fluorescent conjugate is based on a

highly convergent and flexible approach which enables the rapid chemical modification of the AB ring system of this fragile pentacyclic alkaloid, aimed at introducing an anchoring point to graft the fluorophore. The selection of a fluorescein analogue as the reporter group has enabled us to get the first green-emitting CPT conjugate exhibiting valuable spectral properties and retaining biological properties of native CPT. Indeed, in biological models, *i.e.*, glioma cell lines U87 and/or T98, the kinetic of cell endocytosis as well as the efficacy of CPT-FI were compared to those of CPT. CPT-FI fluorescence was measured in the cytosolic compartment of T98 glioma cells from 5 min treatment and remained detectable until 48 h. As CPT, CPT-FI drastically inhibited glioma growth and cell cycle but exhibited a reduced affinity as compared to the native CPT. In vivo and ex vivo imaging studies of CPT-FI intratumoraly injected into a model of NIH-3T3 murine tumor xenografts in nude mice, showed that 24 11 accumulation around the injected site area, which is very promising to target tumors and follow biodistribution in vivo.

Introduction

Since its first discovery in 1966,¹ the pentacyclic alkaloid 20(S)-camptothecin has emerged as an 32 14 important lead compound in the field of anticancer drug development. CPT acts by stabilizing the DNA-37¹⁶ topoisomerase I binary complex and enhancing apoptosis through blocking the advancement of replication forks.² Also, CPT and its numerous derivatives developed over the years, display various 39 17 antitumor activities in a wide range of cancers, such as ovarian and lung (topotecan), colon (irinotecan) or brain (gimatecan and belotecan).^{3,4,5} Despite significant progress, residual secondary effects are still 44 19 46 20 observed, such as for example hematological toxicity, headache, fever and fatigue, associated with the CPT-based chemotherapy. Fluorescent labeling of biomolecules or bioactive compounds is a common 51 22 way to gain insights into either unwanted organism-drug interactions or pharmacological 53 23 mechanisms.^{6,7,8} However, despite the number of questions concerning the pharmacokinetic, real access 56 24 and penetration in the tumor and the number of side effects of usual chemotherapy (as well as new targeted therapies), strategies for fluorescently labeling of cancer therapeutic drugs have scarcely been 58 25

Page 3 of 40

Bioconjugate Chemistry

developed until now. Thus, we propose here the first strategy to develop original imaging tools, adapted

to *in vivo* imaging of the small animal, but also to study mechanisms of action of molecules at the cellular level within tumors (role in apoptosis, proliferation, and vascularization) and in healthy tissues. Despite the overwhelming number of CPT analogues reported in the literature over the past decade, none of them has already been directly modified⁹ with a fluorescent reporter group.^{10,11,12} This can be mainly explained to the absence of a suitable bioconjugatable reactive handle within this pentacyclic alkaloid structure whose derivatization would not drastically affect its biological activity.¹³ In addition, the facile hydrolysis of its lactone moiety represents a challenging bioconjugation issue especially for considering further functionalization of this fragile molecular scaffold. Although most of CPT derivatives exhibit a natural and strong blue fluorescence, their absorption and emission spectra (e.g., shape, intensity and wavelength) are highly dependent on the analogue considered and the stability of their crucial E-ring lactone. Indeed, under physiological conditions, the lactone ring of CPT is rapidly hydrolyzed into the usually less fluorescent and physiologically active carboxylate form.^{14,15,16} Even if the intrinsic fluorescence properties of CPT could be compatible with *in vitro* bioassays,¹⁷ more challenging bio-analytical applications focusing on the tracking of biological events (following administration of this bioactive compound) in cellulo or in vivo could not be easily implemented due to the blue light absorption and scattering by the biological matrix and the background signal from cellular autofluorescence.¹⁸ Thus, it is essential to dispose of a reliable fluorescent chemical reporter conveniently link to the bioactive alkaloid, to efficiently track the biological processes, whatever the analogues considered and its lactone form proportion in biological media. Consequently, in this present work, we wish to provide a general framework to access to a fluorescently-labeled CPT in order to validate the possibility of fluorescently modified chemotherapy (or targeted therapy) without losing valuable and characteristic biological anti-tumoral properties, determined in vitro and in vivo in animal models.

26 Experimental Procedures

General

All solvents were dried following standard procedures (dichloromethane (CH₂Cl₂): distillation over P₂O₅, acetonitrile (CH₃CN): distillation over CaH₂, THF: distillation over Na^o/benzophenone). N,Ndimethylformamide (DMF) was purchased from Fisher Scientific and stored over 3Å molecular sieve. 1,2-Dimethoxyethane (DME) was dried by storage over 3Å molecular sieve. N.N-Diisopropylethylamine (DIEA) was distilled over CaH₂. Column chromatography purifications were performed on Geduran[®] Si 60 silica gel (40-63 µm) from Merck. TLC were carried out on Merck DC Kieselgel 60 F-254 aluminum sheets. Compounds were visualized by one or more of the following methods: (1) illumination with a short wavelength UV lamp (i.e., $\lambda = 254$ nm), (2) spray with a 0.2% (w/v) ninhydrin solution in absolute ethanol, (3) spray with a 3.5% (w/v) phosphomolybdic acid 24 11 solution in absolute ethanol. The HPLC-gradient grade acetonitrile (CH₃CN) and methanol (CH₃OH) were obtained from VWR. Phosphate buffered saline (PBS, 100 mM phosphate + 150 mM NaCl, pH 7.5) and aq. mobile-phases for HPLC were prepared using deionized water purified with a Milli-Q 31 14 system (purified to $18.2 \text{ M}\Omega.\text{cm}$).

Instruments and methods: Melting points were recorded on a LEICA VMHB Kofler system at 36 16 atmospheric pressure. Optical rotations were measured by using a Perkin Elmer 341 polarimeter. 38 17 Infrared (IR) spectra were recorded with a universal ATR sampling accessory on a Perkin Elmer FT-IR Spectrum 100 spectrometer. The elemental analyses were carried out with a Flash 2000 Organic Elemental Analyzer (Thermo Scientific). ¹H and ¹³C NMR spectra (C13APT or C13CPD experiments) 43 19 ⁴⁵ 20 and recorded either on a Bruker AC 200 or on a Bruker DPX 300 spectrometer working at 200 and 300 MHz respectively. Chemical shifts are expressed in parts per million (ppm) from the residual nondeuterated solvent signal CDCl₃ ($\delta_{\rm H} = 7.26$, $\delta_{\rm C} = 77.00$) or DMSO- d_6 ($\delta_{\rm H} = 2.50$, $\delta_{\rm C} = 39.43$).¹⁹ J values 50 22 are in hertz (Hz). Analytical HPLC was performed on a Thermo Scientific Surveyor Plus instrument 55 24 equipped with a PDA detector. Semi-preparative HPLC was performed on a Thermo Scientific 57 25 SPECTRASYSTEM liquid chromatography system (P4000) equipped with a UV-visible 2000 detector. Low-resolution mass spectra were obtained with a Finnigan LCO Advantage MAX (ion trap) apparatus

Page 5 of 40

Bioconjugate Chemistry

equipped with an electrospray (ESI) source. High-resolution mass spectra were recorded on a LCT Premier XE benchtop orthogonal acceleration time-of-flight (oa-TOF) mass spectrometer (Waters Micromass) equipped with an ESI source and in the positive mode. The absorption spectra were recorded on a Varian Cary 50 scan spectrophotometer by using a rectangular quartz cell (Varian, standard cell, Open Top, 10×10 mm, 3.5 mL). The emission/excitation spectra were recorded with a Varian Cary Eclipse spectrophotometer after excitation/emission at the suitable wavelength (excitation and emission filters: auto, excitation and excitation and emission slit: 5 nm) with a semi-micro quartz fluorescence cell (Hellma, 104F-QS, 10×4 mm, 1400 µL). All fluorescence spectra were corrected. The following equation was used to determine the relative fluorescence quantum yield:

 $\Phi F(X) = (AS/AX)(FX/FS)(nX/nS)2 \Phi F(S)^{20}$

Where A is the absorbance at the excitation wavelength. (in the range 0.01-0.1 A.U.), F is the area under the corrected emission curve, n is the refractive index of the solvents (at 25 °C) used in measurements, and the subscripts S and X represent standard and unknown, respectively. The following standards were used: 7-hydroxycoumarin in PBS ($\Phi F = 76\%$) and fluorescein in aq. 0.1 M NaOH ($\Phi F = 90\%$).

RP-HPLC separations: The following system was used for the analytical experiments: column Thermo Hypersil GOLD C_{18} (5 µm, 4.6 × 150 mm) with CH₃CN and aq. 0.1% trifluoroacetic acid (aq. TFA 0.1%, pH 2.0) as eluents [100% TFA (1 min), then linear gradient from 0 to 80% (45 min) of CH₃CN]. UV detection at 254 nm. The following chromatographic system was used for the purification step: column Varian Kromasil C_{18} (10 µm, 21.2 × 250 mm) with CH₃CN and aq. TFA 0.1% as eluents with the following gradient [100% TFA (5 min), then linear gradient from 20 to 100% (49 min) of CH₃CN] at a flow rate of 20.0 mL/min. Double UV detection was achieved at 368 and 456 nm.

Pyridone (3). This compound was prepared in 96% e.e. according to the Fang modification²¹ of Comins'strategy. The e.e. was determined using HPLC equipped with an analytical column Chiralcel

ODH as chiral stationary phase: eluent system: heptane/isopropanol 9/1; flow: 1 mL/min; UV detection:

254 nm; retention times: $t_{R1} = 17.94$ min (area 1 = 1.95) and $t_{R2} = 22.86$ min (area 2 = 98.05).

2-Chloro-6-hydroxyquinolin-3-carbaldehyde (5). To a stirred solution of 2-chloro-6-methoxyquinolin-3-carbaldehyde (500 mg, 2.26 mmol) in dry CH₂Cl₂ (15 mL) cooled at -78 °C was added BBr₃ (0.75 mL, 7.91 mmol, 3.5 equiv.) dropwise. After stirring for 30 min at -78 °C, the mixture was warmed to rt and stirred for further 2 h. Thereafter, the reaction mixture was cooled to 0 °C and quenched by adding ice and cold deionised water. The resulting mixture was extracted with ethyl acetate $(2 \times 50 \text{ mL})$. The combined organic layers were washed with brine, dried over anhydrous MgSO₄ and concentrated under reduced pressure. The resulting residue was triturated with CH₂Cl₂ to afford a yellow solid (380 mg, 1.83 mmol, yield 82%). Mp 210 °C (decomposition). IR 3278, 1693, 1579, 1500, 1219 cm^{-1} . ¹H NMR (300 MHz, DMSO- d_6) $\delta 10.50$ (s, 1H, OH), 10.35 (s, 1H), 8.79 (s, 1H), 7.90 (d, J =24 11 ²⁶ 12 9.0 Hz, 1H), 7.52 (dd, J = 2.4, 9.0 Hz, 1H), 7.43 (d, J = 2.4 Hz, 1H). ¹³C NMR (75.5 MHz, DMSO- d_6) δ 189.4, 156.7, 145.3, 143.6, 139.3, 129.2, 127.7, 126.0, 125.9, 110.2. HPLC $t_{\rm R} = 16.1$ min, purity > 96%. 31 14 MS(ESI+):m/z (%): 208 (100) [M + H]⁺, calcd for C₁₀H₆ClNO₂: 208.

6-(2-Azidoethoxy)-2-chloro-quinolin-3-carbaldehyde (6). To a stirred solution of 5 (100 mg, 0.48 mmol) in dried DMF (1.5 mL), under atmosphere of Argon, at rt was added anhydrous solid K₂CO₃ 36 16 38 17 (333 mg, 2.4 mmol, 5 equiv.). The reaction mixture turned red immediately. After 5 min stirring at room temperature, the azide (126 mg, 0.60 mmol, 1.25 equiv.) was added to the solution. The reaction 43 19 mixture was heated at 50 °C for 12 h. The mixture was cooled to room temperature, solubilized in a ⁴⁵ 20 minimum of water/DMSO (1:1) and directly filtered over silica gel (EtOAc/cyclohexane 1:1) to afford the 2-azidoethyl ether 6 (143 mg, 0.52 mmol, 63%) as a yellow solid. Mp: 124-126 °C. IR 2928, 2118, 1690, 1577, 1497, 1236 cm⁻¹. ¹H NMR (200 MHz, DMSO- d_6) δ 10.33 (s, 1H), 8.74 (s, 1H), 7.91 (d, J =50 22 9.0 Hz, 1H), 7.65 (d, J = 2.6, 1H), 7.57 (dd, J = 2.6, 9.0, 1H), 4.30 (t, J = 4.6 Hz, 2H), 3.76 (t, J = 4.655 24 Hz, 2H). ¹³C NMR (50 MHz, DMSO-*d*₆) δ 189.3, 156.7, 146.5, 144.5, 139.5, 129.2, 127.4, 126.2, 125.9, 108.5, 67.2, 49.2. HPLC: $t_{\rm R} = 24.9$ min, purity > 92%. MS(ESI+): m/z (%): 277 (100) [M + H]⁺, calcd 57 25

(6-(2-Azidoethoxy)-2-chloroquinolin-3-yl)methanol (7). To a stirred solution of 6 (164 mg, 0.59 mmol) in 4 mL of CH₃OH/CH₂Cl₂ (1:1) at 0 °C was added solid NaBH₄ (22 mg, 0.59 mmol, 1 equiv.). The reaction mixture was warmed to rt and stirred for 3 h. Then the solution was quenched with a solution of sat. aq. NH₄Cl (20 mL) and extracted with EtOAc (3×40 mL). The combined organic layers were washed with brine (20 mL), dried over anhydrous $MgSO_4$ and filtered, and the solvent was removed under reduced pressure. The resulting residue was dissolved in a minimum of DMSO and purified by chromatography over silica gel (CH₂Cl₂ then cyclohexane/EtOAc 1:1) to afford the alcohol 7 (123 mg, 0.44 mmol, 74%) as a yellow solid. Mp: 150-152°C. IR 3383, 2928, 2107, 1621, 1497, 1221 24 11 cm^{-1} . ¹H NMR (300 MHz, DMSO- d_6) δ 8.31 (s, 1H), 7.83 (d, J = 9.0 Hz, 1H), 7.48 (s, 1H), 7.37 (d, J =9,0, 1H), 5.72 (s, 1H), 4.66 (s, 2H), 4.29 (s, 2H), 3.74 (s, 2H). ¹³C NMR (75.5 MHz, DMSO-*d*₆) δ 156.3, 145.8, 141.8, 134.6, 134.0, 129.0, 128.2, 122.1, 106.8, 67.0, 59.8, 49.4. pyranol[3,4-c]pyridine-3,8-dione (8). To a stirred solution of 3 (54 mg, 0.26 mmol) in dry DME (4 mL) at 0 °C was added anhydrous tBuOK (32 mg, 0.28 mmol, 1.1 equiv.). The resulting mixture was stirred at 0 °C for 15 min and at rt for further 15 min. A solution of the benzyl bromide 2 (97 mg, 0.28 mmol, 1.1 equiv.) in dry DME (2 mL) was added to the previous solution, and the resulting reaction mixture was stirred for 12 h at rt and 1 h under reflux (for a complete conversion). Thereafter, the mixture was cooled to rt and concentrated. The residue was filtered over a silica gel pad (cyclohexane/EtOAc 1:1 then EtOAc) to afford 8 (73 mg, 0.15 mmol, 60%) as a white solid; Mp: 82-84°C. IR 3371, 2940, 2109, 1743, 1657, 1599, 1228 cm⁻¹.¹H NMR (300 MHz, CDCl₃) δ 7.98 (s, 1H), 24 11 7.89 (d, J = 9.0 Hz, 1H), 7.62 (d, J = 7.2 Hz, 1H), 7.40 (dd, J = 9.3; 2.4, 1H), 7.05 (d, J 2.4, 1H), 6.58 (d, J 2.4, 1H), 7.58 J 7.2, 1H), 5.57 (d, J 16.2, 1H), 5.45 (d, J = 15.3 Hz, 1H), 5.24 (d, J = 15.3 Hz, 1H), 5.16 (d, J = 16.231 14 Hz, 1H), 4.22 (t, J = 4.8, 2H), 3.78 (s, 1H), 3.66 (t, J = 5.1 Hz, 2H), 1.83 - 1.76 (m, 2H), 0.97 (t, J = 7.2Hz, 3H). ¹³C NMR (75.5 MHz, CDCl₃) δ 173.6, 158.7, 156.9, 149.0, 146.9, 143.3, 138.2, 138.0, 129.7, 36 16 127.9, 127.1, 123.8, 119.1, 105.9, 103.2, 72.1, 67.2, 66.3, 50.4, 49.8, 31.3, 7.6. HPLC: $t_{\rm R} = 23.3$ min, purity > 86%. $[\alpha]^{22}_{D}$ +27° (c 2.7, CHCl₃). HRMS (ESI+): Calc. for C₂₂H₂₁ClN₅O₅: 470.1231; found: 38 17 470.1237.

43 19 (S)-7-(6-(2-*tert*-Butyl ethoxycarbamate)-2-chloroquinolin-3-methyl)-4-ethyl-4-hydroxy-1,7-⁴⁵ 20 dihvdro-4H-pyranol[3,4-c]pyridine-3,8-dione (9). The azide derivative 8 (26 mg, 0.05 mmol) was dissolved in a mixture of EtOAc-CH₃OH (2 : 1, v/v, 3 mL). Di-tert-butyl dicarbonate (24 mg, 0.11 50 22 mmol, 2 equiv.) and Lindlar catalyst (7 mg, 5% by wt.) were sequentially added. The reaction flask was purged and flushed with Ar gas then with H₂ gas. The resulting reaction mixture was stirred at rt under 55 24 an H₂ atmosphere for 12 h. Thereafter, the reaction mixture was filtered through a Celite[®] 545 pad, the 57 25 filter cake was washed with EtOAc (5 mL), and the combined filtrates were concentrated under reduced pressure. The resulting residue was filtered on silica gel pad by using a step gradient of EtOAc (20-ACS Paragon Plus Environment

10-(2-tert-Butyl ethoxycarbamate)-(S)-camptothecin(10). In an oven-dried reaction glass tube, a 24 11 solution of 9 (18 mg, 0.03 mmol) in dry CH₃CN (1 mL) and KOAc (8 mg, 0.08 mmol, 2.5 equiv.) were ²⁶ 12 mixed. Ar gas was bubbled through the reaction mixture for 15 min. Then, (PPh₃)₂Pd(OAc)₂ (4.9 mg, 0.006 mmol, 0.2 equiv.) was added and Ar gas was bubbled again through the reaction mixture for 31 14 further 15 min. The flask was sealed and the reaction mixture was stirred at 100 °C for 18 h. Thereafter, the mixture was allowed to cool at rt and then directly filtered over a silica gel pad by using a step gradient of EtOAc (50-100%) in cyclohexane as the mobile phase to afford the desired fused 36 16 38 17 pentacyclic alkaloid derivative 10 as a yellow light solid (12 mg, 0.02 mmol, yield 71%). IR 3345, 2977, 1755, 1656, 1502, 1238 cm⁻¹. ¹H NMR (300 MHz, CDCl₃) δ 8.19 (s, 1H), 8.04 (d, J = 9.3, 1H), 43 19 7.61 (s, 1H), 7.36 (dd, J = 2.1, 9.3 Hz, 1H), 7.06 (d, J = 2.1 Hz, 1H), 5.71 (d, J = 16.2 Hz, 1H), 5.29-⁴⁵ 20 5.20 (m, 4H), 4.22 (s, 1H), 4.16 (t, J = 4.8 Hz, 2H), 3.66-3.62 (m, 2H), 1.94-1.83 (m, 2H), 1.47 (s, 9H), 1.01 (t, J = 7.2 Hz, 3H). ¹³C NMR (75.5 MHz, CDCl₃) δ 173.8, 157.6, 157.5, 155.9, 150.1, 149.9, 146.3, 50 22 144.7, 131.0, 129.5, 129.2, 129.0, 123.3, 118.0, 106.0, 97.4, 79.7, 72.7, 67.5, 66.1, 50.0, 39.9, 31.4, 28.3, 7.8. HPLC: $t_{\rm R} = 23.5$ min, purity > 93%. HRMS (ESI+): Calc. for C₂₇H₃₁ClN₃O₇ : 508.2084; 55 24 found: 508.2090.

57 25 Fluorescein-isonipecotic acid derivative (4). This fluorophore carboxylic acid was prepared according to a procedure recently reported by us²²

Fluorescein-labeled camptothecin (1).

(a) Removal of the Boc group. To a solution of 10 (12 mg, 0.02 mmol) in CH₂Cl₂ (1 mL) cooled at 0 °C was added TFA (0.4 mL, 2.4 mmol, 118 equiv.) dropwise and the resulting mixture was stirred at rt for 2 h. Thereafter, the reaction mixture was concentrated, and the residue was triturated with pre-cooled Et₂O to afford the corresponding TFA salt of amino-camptothecin derivative 11. MS (ESI+): m/z (%): 408 (100) $[M+H]^+$, calcd for C₂₂H₂₂N₃O₅: 408.

(b) Amide coupling reaction. The TFA salt was dissolved in dry DMF (0.6 mL) and the mixture was cooled to 0 °C. Fluorescein carboxylic acid 4 (12.2 mg, 0.03 mmol, 1.2 equiv.), DIEA (20 µL, 0.16 mmol, 7 equiv.), HOBt monohydrate (3.6 mg, 0.03 mmol, 1.2 equiv.), and DCC (6 mg, 0.03 mmol, 1.2 equiv.) were sequentially added. The resulting reaction mixture was stirred at rt for 12 h and then 24 11 evaporated almost to dryness. The resulting residue was purified by semi-preparative RP-HPLC ($t_{\rm R}$ = ²⁶ 12 26.91-29.76 min). The product-containing fractions were lyophilized to afford the desired fluorescent bioconjugate 1 as an orange amorphous powder (7.7 mg, 0.01 mmol, overall yield 40% for the two steps). IR 3353, 2940, 1748, 1594, 1453, 1173 cm⁻¹.¹H NMR (300 MHz, DMSO-*d*₆) δ 8.50 (s, 1H), 31 14 8.10-8.04 (m, 2H), 7.70-7.68 (m, 2H), 7.62-7.60 (m, 1H), 7.52-7.46 (m, 3H), 7.27 (s, 1H), 7.14-7.11 (m, 36 16 2H), 6.78-6.76 (m, 3H), 5.41 (s, 2H), 5.24 (s, 2H), 4.16-4.12 (m, 2H), 4.05-4.02 (m, 1H), 3.52-3.44 (m, 38 17 1H), 3.50-3.45 (m, 2H), 2.36-2.26 (m, 2H), 1.86-1.84 (m, 2H), 1.60-1.56 (m, 2H), 1.22-1.15 (m, 3H), 0.88 (t, J = 6.9 Hz, 3H). ¹³C NMR (75.5 MHz, DMSO- d_6) δ 173.9, 172.4, 166.3, 157.2, 156.7, 156.6, 43 19 150.1, 149.9, 145.6, 143.9, 135.8, 131.6, 130.5, 130.4, 130.2, 130.1, 129.9, 129.6, 129.3, 129.3, 127.1, ⁴⁵ 20 123.0, 120.8, 118.3, 115.2, 106.9, 102.8, 96.0, 72.3, 66.8, 65.2, 50.1, 45.6, 41.0, 37.9, 30.2, 28.4, 27.9, 8.5, 7.7. HPLC: $t_{\rm R} = 21.2$ min, purity > 95%. HRMS (ESI+): Calc. for C₄₈H₄₁N₄O₁₀: 833.2823; found: 50 22 833.2844.

Compounds, cell lines and culture conditions

Bioconjugate Chemistry

NIH3T3 mouse fibroblasts cells (obtained from America Type Culture Collection) were cultured in high glucose DMEM supplemented with 10% fetal calf serum (FBS), 2 mM L-glutamine and 100 U/ml penicillin/streptomycin at 37 °C in a humidified 5% CO₂ incubator. Human cell lines from glioblastoma U87 and T98 were obtained from the American Type Culture Collection. The T98 cells were maintained in HAM-F12 and U87 cells were maintained in DMEM (Invitrogen, Cergy Pontoise, France) containing 10% FBS and 1% sodium pyruvate at 37 °C in a humidified atmosphere containing 5% CO₂. Culture media were replaced every three days.

Topoisomerase I relaxation assay. Topo I inhibitory activity of CPT-FI versus CPT was assayed by supercoiled DNA relaxation assay. Supercoiled DNA (TopoGEN, FL, USA) was incubated at 37°C for 30 min with purified human Topo I (TopoGEN, FL, USA) which was pre-mixed with increasing concentrations CPT-FI (50-200 μ M) or CPT (as control, 50 μ M-1 mM), then terminated with proteinase K/SDS stop buffer, and loaded on to 2% agarose gel. The standard reaction system contained: 0.25 μ g DNA, 10 mM Tris-HCl, pH 7.9, 1 mM EDTA, 150 mM NaCl, 0.1% bovine serum albumin, 0.1 mM spermidine, and 1 U Topo I extracted from T98 cell lines. The samples were electrophoresed in a horizontal 2% agarose gel in TAE (tris base, acetic acid and EDTA) buffer at 1.5 V/cm during 2 h at room temperature. DMSO concentrations in each reaction were maintained at 1 % by the addition of serially diluted drug stocks so as not to produce solvent mediated inhibition of Topo I activity. The gels were only post-stained with ethidium bromide, destained in water and photographed under UV illumination.

0 Cell growth assay

⁵⁰ 21 T98 cells were plated in quadruplicates in 12-well plates (Costar, 15×10^3 cells/well for 24 h before ⁵² 22 treatment in HAM-F12 (for T98 cells) and DMEM (for U87 cells), supplemented with 10% FBS. Cells ⁵⁴ vere then incubated in the absence or presence of graded concentrations of CPT (TCI, Zwijndrecht, ⁵⁶ Belgium) or CPT-FI (0.05 to 5 μ M) for 24, 48, and 72 h, respectively. Controls were determined by ⁵⁹ using a DMSO or FI concentration corresponding to the dilution of CPT used for 5 μ M concentration **ACS Paragon Plus Environment**

tested. After treatment, cells were harvested, rinsed by PBS, detached by accutase (Millipore, Molsheim, France), and cellular density was measured by direct cell counting in tampon Z-tri-Pak (Beckman, Lognes, France) with an electronic cell counter (Z2, Coulter Beckmann).

Cell cycle analysis

36 15

T98 cell lines were plated in 75 cm² flasks (Techno plastic products AG, Trasadingen, Switzerland). When cells reached 80% confluence, they were incubated in the absence or presence of CPT and CPT-FI (50 nM and 0.5 µM) for 24 h or 48 h. Cells treated with DMSO corresponding to CPT concentrations were used as control. Cell cycle analysis was done by DNA staining with propidium iodide by flow cytometry. Briefly, after treatment, cells were trypsinized, harvested in PBS, and fixed in ice cold 70% ethanol for 2 h. Staining was done with 0.6 mg/mL RNase (30 min, RT, Sigma-Aldrich) and 50 µg/mL propidium iodide (30 min, RT, Sigma-Aldrich). Cell cycle status was quantified by FacsCalibur flow 31 13 cytometer (BD Biosciences) using CellQuest analysis software (Becton Dickinson Immunocytometry 14 Systems) using an excitation laser set at 480 nm and a detection wavelength of 670 nm (FL3), to avoid detection of FI excitation.

Imaging of camptothecin-FI incorporation in living cells

46 18 Glioblastoma T98 cell line cultured in glass bottom microwell dishes 35-mm size (MatTek, Ashland, USA) containing growth medium, and maintained in a live cell chamber at a fixed temperature of 37°C. 48 19 ⁵⁰ 20 T98 cellular uptake of CPT and CPT-FI 1 (5 µM) was monitored using a confocal laser-scanning 53 21 microscope TSC SP5 by video time-lapse microscopy at the gain and offset (Leica, Heidelberg, 55 22 Germany) equipped with a AOBS system and a white laser (excitation flexibility).

Bioconjugate Chemistry

The cellular uptake of CPT and CPT-FI was also examined by Flow cytometry. T98 cells were plated in 75 cm² culture flasks containing the growth medium 24 h before treatments with CPT and CPT-FI during 5, 15 and 30 min or 24 and 48 h treatments with CPT and CPT-FI (0.5 µM each). The quantitative fluorescence was observed with a FacsCalibur flow cytometer (BD Biosciences) using CellQuest analysis software (Becton Dickinson Immunocytometry Systems) using an excitation laser set at 480 nm and a detection wavelength of 515 nm, to allow detection of FI excitation.

Heterotopic tumoral growth study

Swiss nude mice (Charles River Laboratory, L'Arbresle, France) were kept in a temperaturecontrolled room (21 ± 1 °C), under an established photoperiod (lights on 07.00-19.00 h) with free access to food and tap water. The work described in this article was carried out in accordance with the Directive 2010/63/EU of the european parliament and of the council of 22th September 2010 on the protection of animals used for scientific purposes, published in the Official Journal of the European Union L276/33 (20.10.2010) and authorized by the French Ethical Committee. These experiments were conducted under the supervision of authorized investigators (H. Castel; authorization no. 76.98 from the Ministry of Food, Agriculture and Fisheries.

For intratumoral experiments, the tumorigenic NIH3T3 cell lines were used to monitor the direct intratumoral penetration of the CPT-FI. Thus, a cohort of 6- to 7-week-old male Swiss Nude mice (Charles River Laboratory, L'Arbresle, France) was sedated by isoflurane inhalation (Aerane, Baxter) and implanted subcutaneously (s.c.) into right flanks with 1×10^6 NIH3T3 cells/100 µL PBS. A stock solution of CPT-FI in DMSO (10⁻² M) was prepared and stored at -20°C. Aliquots of CPT-FI at 40 mg/kg, were freshly prepared in DMSO/NaCl 0.9%, for each day injection. When tumors reached a volume of 700 mm³, 10 µL of CPT-FI or vehicle at the corresponding concentration were injected in the tumor. Tumors sizes were measured every two days by the use of a caliper (Bioblock, 0.01mm precision, Fisher Scientific SAS, Illkirsh, France) and volume was calculated as V = (1/2) a X b2 (a, **ACS Paragon Plus Environment**

length of the apparent tumoral mass; b, width of the apparent tumoral mass). Mice weight was also controlled every two days. Animals were sacrificed when tumors reached the maximal ethical volume of 2000 mm³. Tumors were immediately collected, frozen in isopentane and maintained at -80°C until immunohistochemistry experiments.

For intravenous administration of FITC or CPT-FI, and tumor distribution, a cohort of 6- to 7-week-old male Swiss Nude mice (Charles River Laboratory, L'Arbresle, France) was sedated by isoflurane inhalation (Aerane, Baxter) and implanted subcutaneously (s.c.) into right flanks with 1×10^6 glioblastoma cell line U87 cells/100 µL PBS. A stock solution of FITC or CPT-FI in DMSO (10⁻² M) was prepared and stored at -20 °C. Aliquots of CPT-FI, were freshly prepared in DMSO/NaCl 0.9%, for each injection. When tumors reached a volume of 300 mm³, 100 µL of FITC (66 mg/kg; 0.5 µmol) or 24 11 CPT-FI (66 mg/Kg) were injected via the tail vein. Animals were sacrificed 4 or 8 hours after bolus ²⁶ 12 administration of the fluorescent molecules. Tumors were immediately collected, frozen in isopentane and maintained at -80 °C until immunohistochemical analysis.

Immunohistochemical staining

NIH3T3 Tumor sections (60 µm thick) or U87 tumor sections (60 µm thick) resulting from intravenous exposure to FITC or CPT-FI, were cut in a Cryostat (Cryostat CM1950, Leica 40 17 42 18 microsystèmes, Nanterre, France), mounted on gelatin-coated slides and maintained at -20 °C until experiment. Briefly, slides were first rinsed in PBS, fixed in a paraformaldehyde (PFA) solution (4%, 20 47 20 min, RT) and washed three times in PBS. Sections were permeabilized and pre-incubated in a PBS, BSA 0.1%, NDS, 1:50, Triton X100 0.3%. Slides were then incubated with 4',6-diamidino-2-52 22 phenylindole dihydrochloride (DAPI, 1/1000^e, 10 min, RT, Sigma-Aldrich, Saint Quentin Fallavier, 54 23 France), washed again and mounted in Mowiol 4-88 (Calbiochem, Meudon, France). U87 tumors were co-immunostained with an anti-Collagen IV antibody (Santa Cruz Biotechnology, Le Perray-en-59 25 Yvelines, France), in order to visualize hyperplastic tumor vessels. Slices were then examined using a

Bioconjugate Chemistry

confocal conventional microscope (Leica TCS SP2 AOBS, Nanterre, France) and a macroconfocal
 miscroscope (Leica TCS LSI). Analyses from the confocal acquisitions were achieved by using the
 ImageJ 1.44. software.

Statistical analysis

All statistical analyses were conducted using the GraphPad Prism 4.00 software (GraphPad Software). Among the growth tumoral cell experiments, non-parametric statistical tests were used, *i.e.* Kruskal-Wallis ANOVA and Mann-Whitney tests for dual comparisons. P < 0.05 was considered as significant.

Results and Discussion

To illustrate that proof-of-concept of possible fluorescent modifications of chemotherapy for investigation of biodistribution and pharmacokinetic, the most classical camptothecinoid, 20(S)-camptothecin, was selected as bioactive model compound, along with the well-established fluorescein as the green emitting fluorescent label.²³ Although near-infrared probes are ordinary used for *in vivo* imaging, green fluorescence dyes have been preferred and widely used to image tumors and superficial tissues on small animals such as mice, mainly because of the short penetration distance of green light in tissue.²⁴

To be viable and rapidly extended to a wide range of CPT analogues used as cancer therapy in patients, a late stage modular synthetic approach to the fluorescent conjugate was investigated. Also, it is noteworthy that most of the biologically active analogues are AB and/or E ring modified CPT. Consequently, the synthetic route chosen for the construction of the fluorescent conjugate involves the sequential and late stage assembly of three distinct molecular units: the AB ring system **2** with DE pyridinone-based heterocycle system **3** (described by Comins)²⁵ and finally the subsequent peptide-type coupling reaction between the pentacyclic alkaloid formed and the fluorophore **4** (Fig. 2). The use of an unusual fluorescein derivative bearing a tertiary amide of isonipecotic acid at the 2'-position instead of ACS Paragon Plus Environment

the current carboxyl group was preferred to provide steric protection and so to improve the photostability of the fluorescein core.²⁶ Furthermore, this is the most common way to avoid the undesired cyclization equilibrium leading to the formation of the colorless and non-fluorescent spirolactone (especially at pH < 6). This fluorescein derivative exhibits valuable fluorescence properties in the green spectral region and was attached at the C10 position of the A-ring of the bioactive compound to retain the biological activity. Indeed, substitution on rings C,D and E are usually not well tolerated,¹³ and introduction of an electron-rich function at C10 position does not alter the biological activity of CPT, as illustrated by the C10 phenol substitution found in the topotecan structure (Figure 1).

The DE ring fragment **3** was prepared from 2-methoxypyridine according to the Fang modification of Comins'strategy in 96% e.e (Scheme 1, part 1).²¹ The AB building block **2** was synthesized in four steps 24 11 ²⁶ 12 from commercially available 2-chloro-6-methoxy-3-quinolinecarboxaldehyde (Scheme 1, part 2). First, deprotection of the aromatic methyl ether was achieved with BBr₃ in dry CH₂Cl₂ to afford 5 in 82% yield. Next, the resulting phenol derivative was reacted with 2-azidoethyl tosylate²⁷ in a standard $S_N 2$ 31 14 reaction to give the corresponding ether 6. It is noteworthy that the azido group has proven to be a particularly useful amine precursor due to its good stability under both acidic and basic conditions 36 16 38 17 required for the next steps of the synthesis. The aldehyde 6 was readily reduced with NaBH₄ in CH₂Cl₂-MeOH leading to the corresponding alcohol 7 in a good 74% yield. Final treatment of the primary 43 19 alcohol with phosphorus tribromide in dry CH₂Cl₂ afforded the AB fragment 2 with 65% yield.

The two fragments 2 and 3 were joined as described, on treatment with t-BuOK in 1,2-50 22 dimethoxyethane (DME) to provide the tetracycle 8 (Scheme 2). However, the Heck ring-closure strategy failed to form the C ring system, whatever the reaction conditions tested, probably due to the 55 24 presence of the azido functionality. However, the use of Lindlar catalyst along with (Boc)₂O directly 57 25 and chemoselectively reduced azido 8 into the corresponding N-Boc-protected amine 9 in almost quantitative yield (93%), without dehalogenation of the aromatic chloride.²⁸ Gratifyingly, the Heck

ACS Paragon Plus Environment

Page 17 of 40

Bioconjugate Chemistry

reaction proceeded to afford the corresponding pentacyclic alkaloid 10 in a good 71% yield. Next, the Boc group was removed with trifluoroacetic acid (TFA) in CH₂Cl₂ to furnish the corresponding primary amine 11. The amine-reactive labeling reagent 4 derived from fluorescein was prepared using an optimized (two-step) procedure inspired by the work of Gao et al. (Scheme 3).²⁶ Amidification of fluorescein with tert-butyl isonipecotate was readily achieved by treatment with DCC-HOBt in dry DMF. Thereafter, the *tert*-butyl ester was removed by TFA in CH₂Cl₂. Due to the high polarity of the resulting carboxylic acid derivative, a purification by semi-preparative RP-HPLC was found more convenient than standard chromatography over silica gel. Thus, fluorescein 4 was obtained with a good 43% overall yield. Compared to the synthetic protocol reported by Gao et al.²⁶ which involves the chromatographic isolation of the N-hydroxysuccinimidyl ester (NHS ester) of fluorescein prior to its aminolysis with an alkyl isonipecotate derivative, our synthetic alternative significantly improved the yield and shortened the overall duration of the synthetic process.²² Finally, this fluorescent carboxylic acid was coupled to the primary amino group of 11 under standard peptide-coupling conditions. In our case, DCC-HOBt in the presence of DIEA was preferred to a phosphonium or an uronium salt (such as BOP or TSTU) because these latter coupling reagents are prone to react with the phenol group of fluorescein to give undesired side-products leading to a dramatic drop in the isolated yield for the targeted fluorescent compound. The formation of the CPT-fluorescein conjugate 1 (CPT-FI) was carefully checked by analytical RP-HPLC to avoid over-coupling reaction between the product 1 and the unreacted fluorescein 4. Upon completion of the conjugation reaction, the crude mixture was directly purified by semi-preparative RP-HPLC to isolate pure compound 1 in a satisfying 40% yield over 2 steps. Its structure was confirmed by various spectroscopic data and its high purity was checked by RP-HPLC (see Supporting Information). Analysis of 1 using ESI mass spectrometry indicated the covalent attachment of the fluorescein label and confirmed the integrity of the pentacyclic scaffold of CPT. Thus, the first synthesis of CPT-FI was achieved in 11 steps and 1.4% overall yield from commercial 2-methoxypyridine and 15.8 % from the known pyridinone 3.

The fluorescent probe 1 in hand, its complete photophysical properties were determined, along with those of 4 and 11 (Table 1 and Figure 3), under simulated physiological conditions (*i.e.*, phosphate buffered saline (PBS), pH 7.5), to ensure that the spectral properties of the fluorescein core were kept upon its conjugation to the CPT alkaloid scaffold. As expected, the UV-vis absorption spectrum of the conjugate 1 was the sum of CPT derivative 11 and fluorescein 4 (Fig. 3a), that suggests very weak or no electronic interaction (e.g., ground-state dimer) between these two fluorophores in the ground state. Although the fluorescein derivative 1 displays a smaller fluorescence quantum yield of 37% compared to the parent free xanthene dye 4, satisfyingly, its emission and excitation spectra of 1 are in good agreement with those recorded for 4 or those generally reported for fluorescein derivatives such as 4 (Figure 3b). Consequently, as anticipated and experimentally-validated, the fluorescein part of the 24 11 chromophoric pair 1 could be selectively excited at 480 nm demonstrating attractive spectral factures suitable for further biological imaging applications (Figure 3a). Finally, for informative purpose, the ability of the CPT part of the probe to transfer energy to the fluorescein moiety was also investigated. 31 14 Indeed, as illustrated in Figure 3a, upon excitation at 350 nm (absorption maximum of CPT core), CPT-FI exhibits a strong green emission band centered at 524 nm and a weak blue emission band at 424 nm, 36 16 indicating energy transfer between these two FRET partners with efficiency up to 91% (see Supporting 38 17 Information for details about the energy transfer efficiency (E. T. E.) calculation).

43 19 Next, biological properties of the conjugate 1 were investigated and compared with the CPT of ⁴⁵ 20 interest, 20(S)-camptothecin. In order to verify whether CPT-FI exhibited a similar CPT-inhibitory activity on Topoisomerase I (TOPO I) activity, we first extracted nuclear proteins from T98 cells and 50 22 then evaluated the respective roles of CPT and CPT-FI on TOPO I activity. Then, we showed that T98 nucleus lysates converted a majority of supercoiled DNA into relaxed DNA as observed in lanes 2 and 3 55 24 (Fig 4A and B). Increasing concentrations of CPT (50 to 1000 uM) and CPT-FI (50-200 uM) prevented 57 25 the super coiled DNA from being converted into relaxed DNA (Fig 4A and B), CPT-FI being more efficient than CPT in reproducible experiments. Thus, we demonstrate that CPT-FI exhibit a very potent ACS Paragon Plus Environment

inhibitory control of TOPO I from T98 suggesting that the linker modification of CPT to cross FITC
 would have even favor CPT affinity for TOPO I.

The prolonged exposure of proliferating and/or tumoral cells to topoisomerase inhibitors as CPTderivatives results from DNA alteration and apoptotic events.^{29,30,31} Accurate evaluation of the impact of CPT-FI as efficient anti-neoplasic compound, passed first through measurement of drug distribution using in vitro model systems, as a more practical method of determining how efficiently a drug penetrate cells. Thus, we first compared the kinetics of incorporation of CPT and CPT-FI in cultured human glioblastoma cell line T98. CPT-FI (0.5 µM) was shown to be rapidly internalized (short-term, Figure 5a) in T98 cells after 5 min-treatment, and appeared persistently cell-captured from 24 to 48 h (long-term, Figure 5b), yielding a 10-fold increase in intracellular intensity value from 5 min to 48 h treatment (Figure 5c). We then performed time-lapse confocal microscopy of CPT-FI (5 µM) incorporation into living T98 cells. When extracellularly applied, the fluorescence was detected after 5 min of exposure, as revealed by punctuate fluorescent dots detected around cell nuclei (Figure 5f). As expected, upon excitation laser set at 480 nm, the autofluorescence of CPT could not be detected neither at 5 min nor 30 min post-incubation as shown in Figure 5e (see Supporting Information). Retention in tumor cells can be due to binding at the site of lethal activity (usually DNA), although basic drugs can be sequestered in acidic organelles such as perinuclear endosomes.

We thus hypothesize that specific labeling of CPT with FI may increase fluorescence intensity and/or
facilitate detection with microscopic available equipments facilitating the detection by optical imaging.

Then, we compared the impact of CPT and CPT-FI analogues on growth of the glioblastoma U87and T98 human cell lines from 24 to 72 h of treatment. Both cell lines were exposed to increasing concentrations yielding dose-dependent proliferation rate inhibition starting from the 24 h treatment. Phase contrast microphotographs of non-treated T98 glioblastoma cell lines, showed an adherent monolayer of polygonal cells (Figure 6a). In the presence of CPT, and in a lesser extent, CPT-FI, there was a morphological response characterized by cytoplasm retraction and rounding up of the cell body, **ACS Paragon Plus Environment**

compared to untreated cells (0) (Figure 6a). These effects were accompanied by a modified glioma cell morphology and integrity, suggestive of a drastic impact of the two CPT analogues on human glioma growth and apoptosis. Moreover, the strong CPT-FI staining observed at 5 μ M could be assigned to their aggregation (c.f. Supporting Information for comparative solubility studies between CPT-FI and CPT). As shown in Figure 5b, the dose-response curves indicate that CPT efficiently decreased cell growth from the 0.05 µM concentration. Likewise, CPT-FI showed significant cytotoxic effects on the two cell lines in time and dose-dependent manners (Figure 6b and c).

CPT and CPT-FI showed cytotoxicity, causing anti-proliferating activity in glioma cell lines in a dose and time-dependent manner. CPT-FI exhibiting more than a 10 fold decrease of the CPT efficiency in T98 and retaining equivalent activity in U87. These observations show a real interest for a use of the CPT-FI for body distribution and understanding of exposed non-cancerous organs.

28 12 In order to verify whether morphological changes and cell growth inhibition observed after CPT-FI may be associated to topoisomerase and DNA duplication arrest, cell cycle was investigated in T98 in 33 14 the absence or the presence of both CPT and its derivatives (Figure 7). The cell cycle distribution of the 35 15 T98 glioblastoma cell line was examined *via* flow cytometry, in the absence or the presence of CPT $(0.05 \text{ and } 0.5 \ \mu\text{M})$ after 24 h treatment, or CPT-FI (0.05 and 0.5 \ \mu\text{M}) after 24 h and 48 h treatment. At 40 17 24 h, CPT induced a dose-dependent increase of the G2/M phase from 13% (control) to 24% (0.05 μ M) 42 18 and 73% (0.5 µM), accompanied by a decrease of cell populations in the S phase of the cell cycle, from 17 to 11% (Figure 7a). In contrast, CPT-FI failed to markedly alter cell cycle after 24 h, but evoked a 47 20 CPT-like G2/M cell accumulation after 48 h treatment (Control, 15%; 0.05 µM, 19%; 0.5 µM, 43%) (Figure 7b). CPT-FI exhibits inferior cytotoxic effect than CPT partly due to its lower solubility in 52 22 physiological pH. Indeed CPT-FI markedly precipitates at 5 μ M (40%) at while this phenomenon was 54 23 observed from 10 µM with CPT (c.f. Supporting Information). This observation suggests that we compare the effects of 5 μ M CPT with those of 3 μ M CPT-FI on cell cycle and toxicity. Besides it has 59 25 been reported that substituents at position 10 of the quinoline part of the CPT derivatives may interact

Page 21 of 40

Bioconjugate Chemistry

with the receptor site with the drug binding site of topoisomerase I cleavage complexes.^{32,13} While small substituents at 10 position of the A ring generally increase efficacy in DNA topoisomerase I inhibition, the presence of bulkier groups should more lead to diminished inhibitory activity. Interestingly, the modification of CPT presented here to bear a bulky fluorescein derivative, displays a better affinity toward topoisomerase I than the native CPT. However, we observed *in cellulo* activity of CPT-FI lower than the unmodified CPT, likely attributed to a less hydrophobic properties and reduced membrane penetration, to reach the cell nulei. Together these results thus confirm that CPT induced accumulation in G2/M and T98 glioblastoma cell arrest, and also demonstrate that CPT-FI provokes similar effects but requires longer incubation time and/or higher concentration, establishing the anti-cancer efficiency *in vitro* of the CPT-FI derivative.

Unfortunately, most drugs are not amenable to direct in vivo follow-up because they lack sufficient color or fluorescent properties except the clinically-used drugs doxorubicin, mitoxantrone and topotecan, which exhibit autofluorescence. But initial evidence for limited penetration through tissue of the commonly used anticancer drug doxorubicin was obtained by studying the distribution of its fluorescence in a multicellular layer model.³³ Here, to further extend the possible use of our CPTfluorescent probe as a cytotoxic drug whose fate can be followed in vivo, intratumoral administrations of CPT-FI (CPT-FI, 5 µM, n=4) were performed once daily during four days in xenogafts of NIH-3T3 murine fibroblastic cells in Nude mice (Figure 8a). As compared to intratumoral injections of PBS/DMSO (sham, n=4, not shown), histological examination of CPT-FI injected tumors revealed that green fluorescence accumulated to the greatest extent at the border of the tumor and near the site of injection (Figure 8a). At higher magnification, CPT-FI appeared to be mainly distributed in lacks area surrounding apparent viable cells whereas PBS injected tumors failed to show any detectable autofluorescence (Figure 8b). Deeper inside the tumor, some CPT-FI green zones would show cytotoxicity and diminished cell viability, and colocalization of the CPT-FI and DAPI stainings in isolated cell, illustrates in vivo intranucleus incorporation (Figure 8c). Thus, confocal images of the

CPT-FI distribution in consecutive sections show that only the tumor area exposed to CPT-FI injections is detectable, suggesting limited penetration of the drug. This restricted diffusion into the tumor may be due i) to rapid uptake of the drug by perivascular cells and ii) mostly by the cellular packing density and the number of adhesions between cells, as recently proposed.³⁴ Thus, intravenous administration strategy was employed to monitor the in vivo behavior of CPT-FI compared to FITC alone and to characterize tumor distribution. FITC (100 µl, n=2) or CPT-FI (100 µl, n=3) solutions at 66 mg/Kg was bolus injected through the tail vein into Nude mice bearing U87 glioblastoma tumors. After 4 and 8 h, tumors were frozen and then analyzed. Confocal microscopic images were acquired 4 h after FITC or CPT-FI injection (Figure 9a). As expected, tumors did not show FITC signal whereas they exhibited very dense green staining in vascular and perivascular compartments after exposure to systemic CPT-FI 24 11 (Figure 9a), and was mainly colocalized with collagen IV (Figure 9b). After 8 h, CPT-FI was not found with collagen IV immunostaining, and was more distributed throughout the glioma tumor parenchyma (Figure 9b). This data clearly indicate that CPT-FI can be delivered via intravenous injection, and that 8 31 14 h after administration, the labeled chemotherapy penetrated into the tumor parenchyma through the leaky tumoral vascular network, particularly dense in glioma tumors. Thus, it can be expected that this 36 16 type of small tagged-anti-cancer molecules, may be more widely dedicated to the study and the 38 17 evaluation of pharmacokinetic, tumor penetration and non-cancerous sites of deleterious side effects.

Conclusions

46 20 In summary, we have described for the first time an original synthetic approach enabling the efficient 48 21 fluorescent labeling of anticancer drug camptothecin which is known to exhibit a moderate chemical stability. The key point was the introduction of an azido-terminated linker onto the C10 position of the 53 23 CPT quinoline ring, which acts as an optimal protecting group for the primary amino group only 55 24 unveiled immediately prior to the final fluorescent labeling based on a peptide-type coupling reaction. Besides, careful functionalization at the C10 position of the pentacyclic alkaloid has shown to preserve

Page 23 of 40

Bioconjugate Chemistry

the essential biological features of the CPT bioactive alkaloid, although longer incubation periods or higher concentrations are required. In addition, we demonstrated the feasibility of using a fluorescent topoisomease inhibitor CPT as a model drug to monitor in real-time cell *in vivo* delivery by fluorescent imaging inducing tumor senescence and arrest of cell growth. This new FI-tagged chemotherapy with similar characteristics as the CPT of interest will be very useful for continuous *in vivo* monitoring of a pseudo- drug upon externally triggered delivery. But mainly, the present aim was to open a new avenue of specific design of anti-cancer molecules as fluorescent probes, for the understanding of specific anticancer effects as well as non-desired effects including anemia, fatigue or cognitive deficits commonly described in patients after chemotherapy.
