C-Functionalized diphosphinomethanide and diphosphine ligands of formula [(PPh₂)₂CX]⁻ and $[(PPh_2)_2C(X)(Y)]$ (X = I, CN, SCN, SePh, Y = H; X = Br, Y = H, Br), coordinated to manganese(I), have been prepared by reaction of the methanide complexes [Mn(L)(CO)₃- $\{(PPh_2)_2CH\}\$ (L = CO, CN^tBu) with the halogen and pseudohalogen molecules Br₂, I₂, BrCN, (CN)₂, (SCN)₂ and ISePh followed, when necessary, by the appropriate basic (KOH) or acidic (HBF₄) treatment.

Introduction

A rich chemistry has been developed around the reactivity of alkali-metal diphosphinomethanides with halides of many metallic and nonmetallic elements (MX_n) .¹ This has led to the preparation of a number of diphosphinomethanide derivatives displaying remarkable features, such as a variety of coordination modes (mono-, bi-, and tridentate through the carbon and phosphorus donor atoms), high coordination numbers,² and the noteworthy stabilization of molecules with elements in low oxidation states, such as those of silicon-(II).³ However, as far as we know, the study of the reactivity of diphosphinomethanide anions with dihalogen molecules themselves (X_2) has been limited to the treatment of lithium bis(diphenylphosphino)methanide with iodine, leading to the formation of PPh₂PCH=PPh₂-PPh₂=CHPPh₂, (Ph₂P)₂C=PPh₂CH₂PPh₂, and (Ph₂P)₂-CHCH(PPh₂)₂, which result from P-P, P-C, and C-C coupling, respectively.^{4,5} Curiously, no halogenation product was isolated from the above reaction. In relation to this, as we will describe throughout this paper, we have found that the reaction of bis(diphenylphosphino)methanide $\eta^2(P,P')$ -coordinated in manganese(I) carbonyl complexes toward dihalogens (Br₂ and I_2) takes place in a very different way, allowing the

formation of new C-halogenated diphosphines derived from dppm, as a result of the chemoselective halogenation at the central carbon atom. We have also extended the study of the reactivity of coordinated diphosphinomethanides to pseudohalogen molecules such as BrCN, (CN)₂, (SCN)₂, and ISePh, which has led to the formation of the new functionalized diphosphinomethanide ligands [(Ph₂P)₂CCN]⁻, [(Ph₂P)₂CSCN]⁻, and [(Ph₂P)₂CSePh]⁻ and their corresponding diphosphines $(Ph_2P)_2C(H)CN$, $(Ph_2P)_2C(H)SCN$, and $(Ph_2P)_2C(H)$ -SePh. Preliminary accounts of some of this work have been published.^{6,7}

Results and Discussion

Reactions of [Mn(CO)₄{(Ph₂P)₂CH}] (2a) and fac- $[Mn(CN^{t}Bu)(CO)_{3}{(Ph_{2}P)_{2}CH}]$ (2b) with Dihalogens. The diphosphinomethanide derivatives 2a,b, which were prepared from the corresponding cationic dppm complexes $[Mn(L)(CO)_3{(Ph_2P)_2CH_2}]ClO_4$ (1a, L = CO; **1b**, $L = CN^{t}Bu$) by treatment with KOH,⁸ readily react with Br_2 or I_2 in CH_2Cl_2 to give $[Mn(L)(CO)_3 \{(Ph_2P)_2C(H)X\}]X_3$ (**3a**, L = CO, X = Br; **3b**, L = CN^t-Bu, X = Br; **3c**, L = CO, X = I; **3d**, $L = CN^{t}Bu$, X = I) (see Scheme 1). These compounds contain the new C-halogenated diphosphines (PPh₂)₂C(H)X, arising from the heterolytic cleavage of the X₂ molecules promoted by the methanide carbon atom. As the ligand $[(PPh_2)_2]$ -CH]⁻ in **2a**,**b** is strongly bonded to manganese through the phosphorus atoms, the halogenation reaction was chemoselective on the methanide carbon atom and did not take place to any extent on the phosphorus atoms,

as does occur in free phosphines.⁹ In contrast with that found by Braunstein et al. in the treatment of Li-[(PPh₂)₂CH] with I₂,⁵ we have not detected in the present reactions any product of oxidative C–C coupling. These authors have proposed that the formation of the tetraphosphine (Ph₂P)₂CHCH(PPh₂)₂ in the above reaction takes place through the radical intermediate [(PPh₂)₂CH]• rather than through a metal—halogen exchange. We think, however, that this last pathway cannot be excluded in view of the formation of [(PPh₂)₂C-(H)X] in our synthetic approach.

It must be noted that, in these reactions, an excess of dihalogen must be employed in order to avoid the formation of a mixture containing, in addition to 3a-

d, some amount of $\mathbf{1a}-\mathbf{d}$ and $[Mn(L)(CO)_3\{(Ph_2P)_2CX\}]$ ($\mathbf{4a}-\mathbf{d}$) (see below) due to proton migration from **3** to **2**. The presence of an excess of X_2 is the reason in every case the counteranion is the species X_3^- and not the monoatomic anion X^- , first formed in the heterolytic cleavage of the X_2 molecule by the diphosphinomethanide ligand.

For **3b**,**d** (L = CN^tBu) two isomers are possible, depending upon whether the arrangement of the halogen on the central carbon atom is syn or anti with respect to the isocyanide ligand. The ¹H NMR data showed that both isomers are present in the reaction mixture, as revealed by the appearance of two triplets at about δ 6 for the P₂C(H)X protons and of two ^tBu singlets (see Table 1). However, when a solution of compound **3b** or **3d** in CH₂Cl₂ was set aside at room

^{*a*} In units of cm⁻¹ (measured in CH₂Cl₂). Abbreviations: v = very, s = strong, m = medium, w = weak. ^{*b*} Chemical shifts (δ) in ppm (measured in CD₂Cl₂); coupling constants in Hz. Abbreviations: s = singlet, t = triplet, br = broad. ^{*c*} These data correspond to the *anti* isomers (see text). Data for the *syn* isomers are as follows: **3b**, 1.15 (s, CN/Bu), 6.11 (t, P₂CHBr, ²J_{PH} = 10); **3d**, 1.11 (s, CN/Bu), 6.09 (t, P₂CHBr, ²J_{PH} = 11); **7b**, 1.18 (s, CN/Bu), 6.98 (t, P₂CH, ²J_{PH} = 9); **9b**, 0.99 (s, CN/Bu), 6.23 (t, P₂CH, ²J_{PH} = 10); **10b**, 0.92 (s, CN/Bu), 5.74 (t, P₂CH, ²J_{PH} = 12). ^{*d*} In CDCl₃.

temperature, successive proton spectra showed slow conversion from one isomer to the other. After several days, only one isomer was present, which could be the one with the halogen arranged anti with respect to the bulky CN^tBu ligand. To confirm this and to gain knowledge about the structural data of the new diphosphine, an X-ray diffraction study was carried out for 3b. A view of the complex cation is depicted in Figure 1, showing the manganese in a distorted-octahedral coordination geometry. As was anticipated, the bromine atom is located anti with respect to the isocyanide ligand, this being due apparently to steric reasons. The C(1)-Br(1) bond length (1.98(1) Å) is typical of bromoalkanes,¹⁰ and the P(1)-C(1) (1.82(1) Å) and P(2)-C(1)(1.83(1) Å) distances are of the same order as those usually found in dppm derivatives (single bond P-C). These data are consistent with a sp³ hybridization for carbon C(1), although the bond angles around this atom $(P(1)-C(1)-P(2) = 99.0(4)^{\circ}, P(1)-C(1)-Br(1) = 120.0$ $(5)^{\circ}$, P(2)-C(1)-Br(1) = 121.4(5)^{\circ} indicate a strongly distorted tetrahedral coordination geometry, arising from the strain introduced by the small bite angle of the diphosphine and from the different size and nature of the carbon substituents.

The diphosphines $(PPh_2)_2C(H)X$ in complexes $3\mathbf{a}-\mathbf{d}$ are able to react with bases in two different ways. In fact the experiments show that both substituents at the central carbon atom, hydrogen and halogen, are elec-

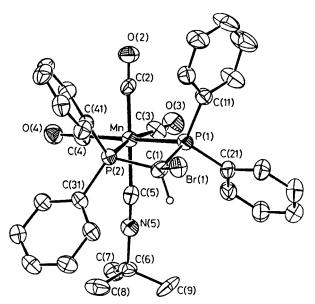

Figure 1. X-ray structure of the cation of **3b**, *fac*-[Mn-(CN^tBu)(CO)₃{(PPh₂)₂C(H)Br}]⁺, showing 30% probability ellipsoids. Selected bond distances (Å) and angles (deg): C(1)-Br(1) = 1.98(1), P(1)-C(1) = 1.82(1), P(2)-C(1) = 1.83(1), Mn-P(1) = 2.299(5), Mn-P(2) = 2.341(4); P(1)-C(1)-P(2) = 99.0(4), P(1)-C(1)-Br(1) = 120.0(5), P(2)-C(1)-Br(1) = 121.4(5), P(1)-Mn-P(2) = 73.6(2).

trophilic in character and can be abstracted as H^+ or X^+ depending upon the nature of the nucleophile used. Thus, the reaction of a dichloromethane solution of **3a**-**d** toward a hard nucleophile such as OH⁻ (from

⁽¹⁰⁾ Trotter, J. In *The Chemistry of the Carbon-Halogen Bond*; Patai, S., Ed.; Wiley: New York, 1973; Part I, p 50.

KOH) takes place with proton abstraction, leading to the formation of $[Mn(L)(CO)_3\{(Ph_2P)_2CX\}]$ (4a–d). However, when a soft nucleophile such as PPh₃ is employed, dehalogenation of the diphosphine immediately occurs to give finally $[Mn(L)(CO)_3\{(Ph_2P)_2CH_2\}]^+$ (1a–d). As shown in Scheme 1, we propose for this last reaction a mechanism involving, in a first step, the formation of $[Mn(L)(CO)_3\{(Ph_2P)_2CH\}]$ (2a–d) and the phosphonium cation $[XPPh_3]^+$, which is acidic enough to protonate 2a–d, affording 1a–d. Supporting this, in an independent experiment we have proved that a dichloromethane solution of 2b readily reacts with freshly prepared $[IPPh_3]^{+}I^{-,11}$ affording 1b, in addition to other phosphorus-containing species which so far remain uncharacterized.

In the ¹³C{¹H} NMR spectra of **4a**–**d** the resonances for the P₂CX carbon atoms appear at remarkably high fields (see Table 1), and the values of ¹*J*_{PC} (about 50 Hz) are much higher than those in **3a**–**d** (about 10 Hz), owing to the higher degree of s character of the central carbon atom in **4** (sp²) compared to that in **3** (sp³).¹²

Although complexes of type 4 are less reactive than **2** toward electrophilic agents, in some cases they are still able to react properly with dihalogen molecules. Thus, the treatment of 4a, b with Br_2 in CH_2Cl_2 causes another heterolytic cleavage of the dihalogen to give the cationic complexes $[Mn(L)(CO)_3\{(Ph_2P)_2CBr_2\}]Br_3$ (**5a**,**b**). In contrast, the reaction of 4c, d with I_2 in CH_2Cl_2 gave an intractable mixture of species, the spectroscopic data of which indicate that double C-iodination of the diphosphine might occur, but only partially. In **5a**, **b** the bromine atoms of the diphosphine are electrophilic, as is proved by their reaction with KOH to afford **4a**,**b**. It must be noted that the diphosphine $[(Ph_2P)_2CBr_2]$ is a curious example of a molecule containing a tetrahedral carbon atom only surrounded by heteroatoms (core P₂-CBr₂).

Reactions of *fac*-[**Mn**(**CN**^t**Bu**)(**CO**)₃{**(Ph**₂**P)**₂**CH**}] (2b) with Pseudohalogens. In the search for new types of functionalized diphosphines and in view of the reactivity of the methanide derivatives **2a**,**b** toward dihalogens, we extended the study of this reactivity to di-pseudohalogen molecules, such as (CN)₂, BrCN, (SCN)₂, and ISePh. We have found that these molecules undergo heterolytic cleavage of C–C, Br–C, S–S, and I–Se bonds, respectively.

The reaction of **2b** with cyanogen leads to the formation of *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CCN}] **(6b)** together with an equivalent amount of the dppm derivative *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CH₂}]⁺ **(1b)** (see Scheme 1). Both complexes are easily separated by column chromatography. On the basis of that found in the reaction of **2b** with dihalogens, we propose that the present reaction takes place through the formation of the cationic intermediate *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C-(H)CN}]⁺ **(7b)** (which is comparable to complexes of type **3**), in which the highly acidic character of the P₂C(H)-CN hydrogen promotes a proton transfer to **2b**, affording the final observed mixture. In fact, the reaction of **6b** with an excess of HBF₄ in CH₂Cl₂ led to the formation of **7b**, which has been spectroscopically characterized but not isolated as a pure compound because it slowly changes to **6b** on removing the excess acid. The IR spectrum of **6b** in CH₂Cl₂, in the region 2200–1800 cm⁻¹, shows, in addition to the ν_{CO} and ν_{CN} bands of carbonyls and isocyanide, a new ν_{CN} absorption at 2143 cm⁻¹ corresponding to the cyano substituent of the methanide. As far as we know, the only complex that has been described previously containing a cyano– diphosphinomethanide ligand is the dinuclear species [Fe₂(CO)₆(μ -PPh₂){ η^2 -(P,P)- μ -(PPh₂)₂CCN}],¹³ which was formed in a rather unexpected way.

The reaction of **2b** with BrCN yields directly the bromination product **4b** and not the cyanation product **6b**. In fact, this is a clean one-step synthetic procedure for obtaining **4b**. Basically, this result can be rationalized by assuming a $Br^{\delta+}CN^{\delta-}$ charge distribution for this reagent, which forces the nucleophilic attack of the methanide to take place on the bromine atom.

The methanide complex **2b** was also able to react under mild conditions with thiocyanogen. (SCN)₂, affording a mixture of the new thiocyanate-diphosphinomethanide derivative fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂-CSCN}] (8b) and the starting dppm complex 1b. After column chromatography, 8b was isolated as colorless crystals. Its spectroscopic data are consistent with a thiocyanate structure for the new ligand, $[(Ph_2P)_2-$ CSCN⁻, rather than its isomeric isothiocyanate form [(Ph₂P)₂CNCS]⁻. Thus, the IR spectrum of **8b** shows a sharp band at 2135 cm⁻¹, which is in the range corresponding to organic thiocyanates.¹⁴ Furthermore, in the $^{13}C{^{1}H}$ NMR spectrum, the resonance of the -SCNcarbon appears as a triplet at δ 117.2 (${}^{3}J_{PC} = 4$ Hz). 14 **8b** readily reacts with HBF₄ to give the cationic complex fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SCN}]⁺ (**9b**), which should be the intermediate species in the formation of **8b**. This was stable enough to be isolated as a white solid, which was fully characterized (see Table 1 and Experimental Section).

Finally, the reaction of **2b** with ISePh promotes the heterolytic cleavage of the I–Se bond to give a mixture of *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SePh}]⁺ (**10b**), *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CSePh}] (**11b**), and **1b**. After treatment with KOH and further column chromatography, **11b** was isolated as a white solid in 80% yield. As expected, a protonation reaction carried out on **11b** with HBF₄ afforded **10b**.

A general consideration to be made regarding all the cationic species *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)CN}]⁺ (**7b**), *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SCN}]⁺ (**9b**), and *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SePh}]⁺ (**10b**) is that they appear as a mixture of two isomers, arising from the relative syn and anti dispositions of the substituent CN, SCN, or SePh of the diphosphine, with respect to the CN^tBu ligand. This is shown by the spectroscopic data of these complexes (see Table 1), especially by the appearance of two P₂C(H)– triplets at about δ 6.5 and two CN^tBu resonances in the proton spectra. However, when it stands in CH₂Cl₂ at room

temperature, the mixture slowly changes to one isomer only, which should be the anti one on the basis of the structure found for the very similar complex **3b** (see above).

Experimental Section

General Comments. All reactions were carried out under a nitrogen atmosphere with the use of Schlenk techniques. Solvents were dried and purified by standard techniques and distilled under nitrogen prior to use. All reactions were monitored by IR spectroscopy (Perkin-Elmer FT 1720-X and Paragon 1000 spectrophotometers). The C, H, and N analyses were performed on a Perkin-Elmer 240B elemental analyzer. ¹H, ¹³C, and ³¹P NMR spectra were measured with Bruker AC-300 and AC-200 instruments. Chemical shifts are given in ppm, relative to internal SiMe₄ (¹H, ¹³C) or external 85% H₃-PO₄ (³¹P). The complexes [Mn(CO)₄{(Ph₂P)₂CH}] (**2a**) and *fac*-[Mn(CNⁱBu)(CO)₃{(Ph₂P)₂CH}] (**2b**)⁸ and the reagents (CN)₂¹⁵ and (SCN)₂¹⁶ were prepared as described elsewhere. All other reagents were commercially obtained and were used without further purification.

[Mn(CO)₄{(Ph₂P)₂C(H)Br}]Br₃ (3a). A solution of [Mn(CO)₄{(Ph₂P)₂CH}] (2a; 0.20 g, 0.36 mmol) in 20 mL of CH₂Cl₂ was added dropwise to an excess of bromine (0.13 mL, 2.54 mmol) at room temperature with continuous stirring. The solvent was then evaporated to dryness and the residue washed with hexane (30 mL) and dried under vacuum. A yellow crystalline solid was obtained (0.30 g, 96%). The product can be recrystallized from CH₂Cl₂/hexane. Anal. Calcd for C₂₉H₂₁Br₄MnO₄P₂: C, 40.04; H, 2.43. Found: C, 40.37; H, 2.34.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)Br}]Br₃ (3b). The procedure is completely analogous to that described above, using *fac*-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CH}] (2b; 0.20 g, 0.33 mmol) and Br₂ (0.12 mL, 2.31 mmol). Yield: 0.26 g (85%). Anal. Calcd for $C_{33}H_{30}Br_4MnNO_3P_2$: C, 42.84; H, 3.27; N, 1.51. Found: C, 42.97; H, 3.24; N, 1.46. Slow diffusion of hexane into a CH₂-Cl₂ solution of the compound afforded yellow crystals suitable for X-ray diffraction study.

$$\label{eq:linear_state} \begin{split} & [Mn(CO)_4\{(Ph_2P)_2C(H)I\}]I_3\ (3c). \ \mbox{This was similarly prepared from $2a$ (0.20 g, 0.36 mmol) and I_2 (0.64 g, 2.54 mmol): red crystals from CH_2Cl_2/hexane. Yield: 0.29 g (76%). Anal. Calcd for $C_{29}H_{21}I_4MnO_4P_2$: C, 32.92; H, 2.00. Found: C, 32.71; H, 1.93. \end{split}$$

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)I}]I₃ (3d). This was similarly prepared from 2b (0.20 g, 0.33 mmol) and I₂ (0.59 g, 2.32 mmol): brown-red solid. Yield: 0.26 g (70%). Anal. Calcd for $C_{33}H_{30}I_4MnNO_3P_2$: C, 35.61; H, 2.72; N, 1.26. Found: C, 35.73; H, 2.68; N, 1.30.

 $[Mn(CO)_4\{(Ph_2P)_2CBr\}]$ (4a). An excess of KOH (1 g) was added to a solution of **3a** (0.2 g, 0.23 mmol) in 20 mL of CH₂-Cl₂. The mixture was stirred until the IR spectrum of the solution showed no bands corresponding to **3a** (2 h approximately). The resulting yellow solution was filtered off and concentrated to 5 mL. Addition of hexane and cooling (-20 °C) gave yellow crystals of the product. Yield: 0.12 g (83%). Anal. Calcd for C₂₉H₂₀BrMnO₄P₂: C, 55,35; H, 3.20. Found: C, 55.31; H, 3.20.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CBr}] (4b). The procedure is completely analogous to that described above, using **3b** (0.25 g, 0.27 mmol) and KOH (1 g). Yield: 0.18 g (90%). Anal. Calcd for $C_{33}H_{29}BrMnNO_3P_2$: C, 57,91; H, 2.05; N, 4.27. Found: C, 57.84; H, 2.15; N, 4.27.

[Mn(CO)₄{**(Ph**₂**P)**₂**CI**}] **(4c).** This was similarly prepared from **3c** (0.15 g, 0.14 mmol). Yield: 77 mg (81%). Anal. Calcd

for $C_{29}H_{20}IMnO_4P_2$: C, 51.51; H, 2.98. Found: C, 51.23; H, 2.80. Pale yellow crystals of $4c \cdot CH_2Cl_2$, suitable for X-ray diffraction study, were obtained by recrystallization from CH_2 - Cl_2 /hexane.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CI}] (4d). This was similarly prepared from **3d** (0.25 g, 0.22 mmol) and KOH (1 g). Yield: 0.15 g (90%). Anal. Calcd for C₃₃H₂₉IMnNO₃P₂: C, 54.19; H, 1.91; N, 4.00. Found: C, 54.01; H, 1.94; N, 3.99.

[Mn(CO)₄{(Ph₂P)₂CBr₂}]Br₃ (5a). A solution of 4a (0.15 g, 0.24 mmol) in 20 mL of CH₂Cl₂ was added dropwise to an excess of bromine (61 μ L, 1.18 mmol). The resulting mixture was stirred for 10 min. The solvent was then evaporated to dryness under reduced pressure. The residue was washed with hexane (20 mL), giving a yellow solid (0.21 g, 93%). The product can be recystallized from CH₂Cl₂/hexane. Anal. Calcd for C₂₉H₂₀Br₅MnO₄P₂: C, 36.71; H, 2.12. Found: C, 36.51; H, 2.08.

fac-[**Mn(CN**^t**Bu)(CO)**₃{(**Ph**₂**P**)₂**CBr**₂}]**Br**₃ (**5b)**. This was similarly prepared from **4b** (0.20 g, 0.29 mmol) and Br₂ (80 μ L, 1.55 mmol). Anal. Calcd for C₃₃H₂₉Br₅MnNO₃P₂: C, 39.48; H, 2.91; N, 1.39. Found: C, 39.57; H, 2.95; N, 1.41.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CCN}] (6b). To a solution of **2b** (0.30 g, 0.49 mmol) in CH₂Cl₂ (25 mL), (CN)₂ was bubbled through. The reaction was monitored by IR spectroscopy, until all the starting material had been consumed (about 1 h). Bands corresponding to **1b** and **6b** were observed. The solution was then evaporated to dryness and the remaining solid chromatographed through an alumina column (activity III). Elution with CH₂Cl₂/hexane (1:2) and evaporation of the solvent give the desired product **6b** as a white solid. Yield: 0.11 g (35%). Anal. Calcd for C₃₄H₂₉MnN₂O₃P₂: C, 64.77; H, 4.63; N, 4.44. Found: C, 64.73; H, 4.64; N, 4.13.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CSCN}] (8b). To a solution of **2b** (0.35 g, 0.58 mmol) in 15 mL of CH_2Cl_2 was added a solution containing (SCN)₂ (45 mg, 0.38 mmol) in 15 mL of CH_2Cl_2 dropwise with continuous stirring. The reaction occurs instantaneously, giving a mixture of **1b** and **8b** (by IR spectroscopy). The solution was then evaporated to dryness and the remaining solid chromatographed through an alumina column (activity III). Elution with CH_2Cl_2 /hexane (1:2) and evaporation of the solvent give **8b** as a white solid. Yield: 0.13 g (34%). Anal. Calcd for $C_{34}H_{29}MnN_2O_3P_2S$: C, 61.64; H, 4.41; N, 4.23. Found: 61.33; H, 4.35; N, 4.12.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SCN}]BF₄ (9b). To a solution of **8b** (0.1 g, 0.15 mmol) in 15 mL of CH₂Cl₂ was added tetrafluoroboric acid-diethyl ether complex (85%; 52 μ L, 0.30 mmol) with stirring. The formation of **9b** takes place instantaneously. The solvent was then evaporated to dryness and the residue washed with diethyl ether (3 × 5 mL). A white solid was formed, which was recrystallized from CH₂Cl₂/hexane. Yield: 96 mg (85%). Anal. Calcd for C₃₄H₃₀BF₄-MnN₂O₃P₂S: C, 54.42; H, 4.03; N, 3.73. Found: C, 54.63; H, 4.20; N, 3.60.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂CSePh}] (11b). A solution of **2b** (0.2 g, 0.33 mmol) in 20 mL of CH_2Cl_2 was added dropwise to ISePh (93 mg, 33 mmol) with continuous stirring. Once the addition was finished, the resulting mixture was treated with an excess of KOH (1 g) and stirred for 30 min. The solution was filtered off and evaporated to dryness to give a pale yellow residue. This was chromatographed through an alumina column (activity III), using CH_2Cl_2 /hexane (1:1) as eluent. Evaporation of the solvent to dryness gave **11b** as a white solid. Yield: 0.20 g (80%). Anal. Calcd for $C_{39}H_{34}$ -MnNO₃P₂Se: C, 61.59; H, 4.50; N, 1.84. Found: C, 61.11; H, 4.58; N, 1.89.

fac-[Mn(CN^tBu)(CO)₃{(Ph₂P)₂C(H)SePh}]BF₄ (10b). This was prepared similarly to **9b**, starting from **11b** (0.10 g, 0.13 mmol) and HBF₄·Et₂O (85%, 45 μ L, 0.26 mmol). Yield: 89 mg (80%). Anal. Calcd for C₃₉H₃₅BF₄MnNO₃P₂Se: C, 55.21; H, 4.16; N, 1.65. Found: C, 55.45; H, 4.28; N, 1.54.

X-ray Crystallography. Crystals of 3b suitable for X-ray diffraction analysis were grown from a dichloromethane solution layered with hexane at 25 °C. Data collection, crystal, and refinement parameters are summarized in Table 2. Unit cell parameters were obtained from the least-squares fit of 25 reflections with θ between 9 and 12°. Lorentz and polarization corrections were applied. The structures were solved by direct methods using SHELXS86¹⁷ and expanded by DIRDIF.¹⁸

Isotropic full-matrix least-squares refinement on F using SHELX76¹⁹ converged to R = 0.17. At this stage additional empirical absorption correction was performed using DI-FABS.²⁰ Maximum and minimum correction factors were 1.00 and 0.35, respectively. All non-hydrogen atoms were anisotropically refined on F² using SHELXL93.²¹ The drawing of the complex shown in Figure 1 was made using EUCLID.22
