ABSTRACT: A process for tunable and chemo-, regio-, and stereoselective photocatalytic trifluoromethylation of styrenes was developed. Thermodynamically stable *E*-trifluoromethylated alkenes were prepared using Togni's reagent in the presence of Ru(bpy)₃Cl₂·6H₂O under visible light irradiation, whereas less thermodynamically stable *Z*-trifluoromethylated alkenes were obtained by employing Umemoto's reagent and photocatalyst Ir(ppy)₃.

INTRODUCTION

The trifluoromethyl group (CF_3) has received increasing attention in organic synthesis¹ because its incorporation into organic molecules often enhances lipophilicity, metabolic stability, bioavailability, and binding selectivity.² Trifluoromethylated alkenes are important structural units that have been widely used in medicinal chemistry³ and material science.⁴ Consequently, a variety of methods have been developed for preparing these compounds (Scheme 1a). The condensation of an aldehyde with a trifluoromethyl-containing building block has been a common synthetic method for developing these alkenes.⁵ The addition reaction of trifluoromethylating reagents to alkynes was evaluated as another direct route to

trifluoromethylated alkenes.⁶ These compounds have also been prepared by indirect approaches, such as transformation from trifluoromethylated alkanes⁷ or alkynes.⁸ Transitionmetal-mediated and -catalyzed cross-coupling reactions of CF₃-substituted alkenes,⁹ and trifluoromethylation of prefunctionalized alkenes,¹⁰ have proven to be powerful synthetic strategies. Over the past two years, direct vinyl C—H trifluoromethylation has received increasing attention^{11,12} because this method is atom- and step-economical. Despite the significant progress that has been made in the synthesis of trifluoromethylated alkenes, little attention has been paid to the control of E/Z selectivity of the products. In most cases, thermodynamically stable E isomers were formed as the major products. Very few methods have been developed for the stereoselective synthesis of Z isomers.¹² The stereoselective synthesis of Z- and E-trifluoromethylated alkenes, especially from the same substrate, has not been explored and remains a big challenge.

Recently, visible light photoredox catalysis has emerged as an important and ecofriendly synthetic tool,¹³ and it has been widely applied for the trifluoromethylation of organic molecules.¹⁴ We wondered if it was possible to selectively synthesize both *Z*- and *E*-trifluoromethylated alkenes from the same substrate via photocatalytic processes. Considering the fact that photoexcited catalysts engage not only in single-electron transfer (SET) but also in triplet-triplet energy transfer (TTET) with organic molecules,^{13f} it might be possible to control the configuration of olefinic products by choosing a proper photocatalyst via different processes (SET or SET/

TTET). In continuation of our research interest in transitionmetal-mediated and -catalyzed trifluoromethylation reactions, ^{6b,10a,15} we herein report a new type of visible lightinduced trifluoromethylation of styrenes using electrophilic trifluoromethylating reagents (Scheme 1b). This protocol accomplished direct C—H trifluoromethylation of styrenes. More importantly, the E/Z configuration of the trifluoromethylated alkenes could be controlled by choosing specific photocatalysts. To the best of our knowledge, this work is the first example of tunable, stereoselective synthesis of trifluoromethylated alkenes.

Our research plan consisted of three steps (Scheme 2a). The first step was to investigate the chemo-, regio-, and stereo-selective synthesis of *E*-trifluoromethylated alkenes via the photocatalytic SET process. In the second step, the TTET process was employed for converting thermodynamically stable *E* isomers into thermodynamically less stable *Z* isomers. The final step focused on a one-pot, tandem SET/TTET reaction for the direct synthesis of less thermodynamically stable *Z*-trifluoromethylated alkenes from styrenes.

The hypothesized reaction process is shown in Scheme 2b. Normally, visible light-induced trifluoromethylation of alkenes using electrophilic trifluoromethylation reagents has been proposed via an oxidative quenching cycle involving SET.^{6c,7a,14f,j} First, irradiation with visible light excited ground state $Ru(bpy)_3^{2+}$ into excited state $Ru(bpy)_3^{2+*}$. SET oxidation of Ru(bpy) $_{3^{2+*}}^{2+*}$ (-0.81 V vs SCE in CH₃CN)¹⁶ by electrophilic trifluoromethylating reagents gave Ru(bpy)3³⁺ and a trifluoromethyl radical. The resulting trifluoromethyl radical was then added to an alkene to generate radical intermediate A. To control the regioselectivity of this addition step, styrene was chosen as the substrate because its neighboring aryl group could stabilize the radical in intermediate A. Subsequent oxidation of intermediate A by a second SET process produced β -CF₃ carbocation intermediate **B**, which ultimately eliminated the proton to stereoselectively generate the thermodynamically stable *E* product.

Compared to the SET catalytic cycle, the TTET catalytic cycle has been less explored.^{13f} In 1973, Wrighton reported that

TTET from Ru(bpy)₃^{2+*} could promote olefinic cis-trans isomerization.¹⁷ Inspired by this work, we decided to select a photocatalyst with higher triplet energy, such as Ir(ppy)₃ (E_T = 2.41 eV),¹⁸ for additional TTET catalytic cycling. The energy from the triplet excited state of Ir(ppy)₃* could promote the transformation of the ground singlet state of *E* alkene into its lowest-energy triplet state C(T₁). The decay of intermediate C gave a photostationary state mixture of *Z* and *E* alkene. If the *E* alkene could absorb the energy from the triplet excited state of Ir(ppy)₃*, the *Z* alkene would be gradually enriched via this catalytic cycle.

RESULTS AND DISCUSSION

We initially examined the photocatalytic trifluoromethylation of styrene **1a** using Togni's reagent $2a^{19}$ in the presence of $Ru(bpy)_3Cl_2\cdot 6H_2O^{6c}$ under visible light irradiation. Unfortunately, the reaction mixture was complex, and the desired product was obtained in low yield. To eliminate the byproducts, which probably formed from intermediates **A** and **B** (Scheme 2b), we decided to introduce an electron-donating group (EDG) into the phenyl ring for chemoselective synthesis of the desired olefinic product. The EDG substituent made intermediate **A** more electron-rich and thus more easily oxidized for the formation of intermediate **B**. Moreover, it was better to attach the EDG substituent at the ortho position to prevent intermolecular nucleophilic attack on the carbocation of intermediate **B**.

On the basis of this consideration, *N*,*N*-dimethyl-2-vinylaniline **1b** was chosen as the substrate for visible light photocatalytic trifluoromethylation (Table 1). To our delight, the desired product **4b** was formed in 81% yield, and no byproduct could be detected from ¹⁹F NMR spectroscopy of the crude product (Table 1, entry 1). This result showed that the substituent of an electron-donating group on the phenyl ring was crucial for the formation of trifluoromethylated alkene. Other electrophilic trifluoromethylating reagents **2b**–**d** were then screened. When Togni's reagent **2a** was used as the CF₃⁺ source, both of the trifluoromethyl-benzoyloxylated products **3a**^{6a} and **4b** were formed in moderate yields (Table 1, entry 2).

^{*a*}Reaction conditions: **1b** (0.1 mmol), **2** (0.12 mmol), $Ru(bpy)_3Cl_2$. 6H₂O (0.002 mmol), solvent (2.0 mL), visible light, room temperature, and under N₂. ^{*b*}Yield determined by ¹⁹F NMR spectroscopy using trifluoromethoxybenzene as an internal standard.

Umemoto's reagents 2c and $2d^{20}$ also gave 4b in good yields, along with a trace amount of byproducts (Table 1, entries 3 and 4). The solvent was crucial to the reaction. When the reaction was performed in other polar and less polar solvents, such as NMP, DMSO, CH₃CN, and CHCl₃, compound 4b was formed in lower yields (Table 1, entries 5–8). It is noteworthy that the alkoxytrifluoromethylated product 3b was produced in 84% yield^{7a} when methanol was used as the solvent (Table 1, entry 9). Finally, the yield of 4b was slightly improved to 86% when the reaction was allowed to proceed for 20 h (Table 1, entry 10).

With the optimized conditions in hand (Table 1, entry 10), the substrate scope of Ru-catalyzed C-H trifluoromethylation of styrenes was investigated (Table 2). In all cases, the E isomer of the trifluoromethylated alkenes was formed exclusively. Styrenes bearing halogen atoms on the phenyl ring (Cl and Br) smoothly produced corresponding products 4g and 4h in good yields. For substrates with an electron-withdrawing group, more catalyst loading (5 mol %) was needed (1j and 1k). The methoxy and benzoxy substituents at the ortho position of styrenes also promoted the formation of olefinic products 41 and 4m in good yields using 2c as the CF_3^+ source. Both pyrrolidinyl and pyperidinyl substituents proved to be effective electron-donating groups, unlike a dimethylamino group, for photocatalytic trifluoromethylation (10 and 1p). Furthermore, trifluoromethylation of an internal alkene (1s) was also successful in giving compound 4s with excellent regio- and stereoselectivity, although the yield was slightly lower than in terminal alkenes.

The second step of our research plan focused on the conversion of the *E*-trifluoromethylated alkenes into the thermodynamically less stable *Z* isomers. Optimization of the reaction conditions for *E* to *Z* isomerization is shown in Table 3. No conversion was found in the presence of $\text{Ru}(\text{bpy})_3\text{Cl}_2$.

 $6H_2O$ under visible light irradiation (Table 3, entry 1). All of the Ir catalysts could promote isomerization, and Ir(ppy)₃ was found to be optimal by giving the highest Z to E ratio (Table 3, entries 2–5). This result was similar to Weaver's recent work²¹ in which Ir(ppy)₃ was used for promoting the isomerization of a thermodynamic E alkene to a less stable Z isomer. When other solvents, such as NMP, DMSO, and CH₃CN, were used, lower Z to E selectivities were obtained (Table 3, entries 6–8). The reaction conditions were further optimized by prolonging the reaction time or decreasing the reaction temperature (Table 3, entries 9 and 10). However, neither of these alterations gave better results. Then, several E-trifluoromethylated alkenes, **4b**, **4c**, **4h**, and **4k**, were investigated for this E to Z transformation using the optimized conditions (Table 3, entry 2). All of the desired Z isomers, **5b**, **5c**, **5h**, and **5k**, were obtained in good yields (Scheme 3). It was noteworthy that Z-trifluoromethylated alkene **5b** was not converted into the E-trifluoromethyalted alkene **4b** under $Ir(ppy)_3$ -catalyzed visible light irradiation.

Scheme 3. Transformation of Compound 4

After the *E*-trifluoromethylated alkenes had been synthesized and transformed from *E* to *Z* isomers, we then attempted onepot synthesis of *Z*-trifluoromethylated alkenes. The reaction conditions were optimized using **1b** as the model substrate and $Ir(ppy)_3$ as the photocatalyst, which was the optimal catalyst as demonstrated in Table 3. First, different electrophilic trifluoromethylating reagents were screened (Table 4, entries

1-4). When Togni's reagent 2a was used, the desired product 5b was formed in 51% yield (Table 4, entry 1). Being the same as the Ru-catalyzed reaction in Table 1, reaction of Togni's reagent 2a gave trifluoromethyl-benzoyloxylated compound 3a as the major byproduct (Table 4, entry 2). Umemoto's reagents 2c and 2d improved the yield of 5b to 72% and 64%, respectively (Table 4, entries 3 and 4). Thus, 2c was chosen as

the trifluoromethylating reagent for $Ir(ppy)_3$ -catalyzed trifluoromethylation. Then, various solvents were investigated, and DMA was found to be better than other solvents tested (Table 4, entries 5–8). Finally, the additives Li_2CO_3 and DBU were added to the reaction mixture to determine if they could improve yield and Z/E selectivity; however, no further improvement was obtained (Table 4, entries 9 and 10). This reaction process was monitored by ¹⁹F NMR spectroscopy of the reaction mixture. It was found that *E* isomer **4b** was the major product formed at the beginning. As time progressed, **4b** was gradually converted to the *Z* isomer **5b** until reaching a final equilibration between **4b** and **5b**.

The substrate scope of Ir-catalyzed C—H trifluoromethylation of styrenes was then investigated. The Z-trifluoromethylated alkenes were obtained in moderate to high yields (Table 5). The trifluoromethylation of styrenes bearing various

electron-donating (methyl and methoxy) and electron-withdrawing (ester and trifluoromethyl) substituents at different positions along the phenyl ring proceeded well. All of the halogen atoms (F, Cl, Br, and I) were also compatible; they gave the corresponding products 5f-i in moderate yields. Other electron-donating groups (e.g., alkoxy and dibenzylamino), unlike a dimethylamino group, could also accelerate the formation of the desired products (51-r). The configuration of

compound **5q** was confirmed by X-ray crystallographic analysis (see Supporting Information).

This photocatalytic protocol could also be applied for direct C—H trifluoromethylation of complex molecules, such as steroid and amino acid derivatives **1t** and **1u** (Scheme 4). The corresponding trifluoromethylated alkenes were isolated in high yields, although the Z/E selectivities were comparably low. These results showed that this reaction might be applicable to "late-stage trifluoromethylation" of natural products and drugs.

Furthermore, pentafluoroethylating reagent 2e was synthesized²² and used for the visible light-induced reaction (Scheme 5). The Ru-catalyzed reaction gave pentafluoroethylated *E*

isomer **6** in 70% isolated yield, whereas the Ir-catalyzed reaction produced Z isomer 7 in 56% isolated yield. These results showed that this photocatalytic protocol could be extended to perfluoroalkylation reactions.

The dimethylamino group could serve as not only an efficient assisting group but also a potential leaving group. For example, treatment of compound **4b** with MeOTf afforded the aryltrimethylammonium triflate intermediate, which then reacted with different nucleophiles, such as methoxide and fluoride anions, to produce the trifluoromethylated alkenes **4l** and **8** (Scheme 6).

CONCLUSION

In summary, we have developed the first example of tunable and chemo-, regio-, and stereoselective synthesis of Z- and Etrifluoromethylated alkenes by means of visible light catalysis.

Scheme 6. Transformation of Compound 4b

The thermodynamically stable E isomers were prepared by direct C—H trifluoromethylation of styrenes promoted by Rucatalyzed SET. A one-pot Ir-catalyzed tandem SET/TTET process was developed for the preparation of thermodynamically less stable Z isomers. This protocol provides a mild and efficient method for direct C—H trifluoromethylation of various styrenes, including some complex molecules. It could also be extended to other fluoroalkylation reactions, such as pentafluoroethylation.

EXPERIMENTAL SECTION

General Experimental Methods. ¹H NMR (TMS internal standard), ¹⁹F NMR (CFCl₃ outside standard, low-field positive), and ¹³C NMR spectra were recorded on a 400 MHz spectrometer. Chemical shifts (δ) are reported in ppm, and coupling constants (J) are in hertz. The following abbreviations were used to explain multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet. HRMS spectra using ESI were obtained on an ESI-FTMS mass spectrometer. Unless otherwise noted, all reagents and substrates were obtained commercially and used without further purification. Substrates **1b**-s,²³ **1t**,²⁴ and compound **1u**²⁵ were prepared according to procedures in the literature. Compounds **1b**,^{26a} **11**,^{26b} **1m**,^{26c} **10**,^{26e} **1q**,^{26e} **1s**,^{26f} and **41**^{26g} are all known compounds.

General Procedure for the Synthesis of Styrenes (1). In a sealed tube, 2-fluorobenzaldehyde (5.0 mmol, 1 equiv) was dissolved in DMSO (10.0 mL) and then K_2CO_3 (15.0 mmol, 3 equiv) and dimethylamine hydrochloride (10.0 mmol, 2 equiv) were added, and the reaction mixture was stirred and heated to 100 °C until the reaction was complete. The reaction mixture was then poured into water and extracted with EtOAc (3 × 30 mL/mmol). The organic layers were combined, dried with MgSO₄, and concentrated under reduced pressure to get the crude product 2-(*N*,*N*-dimethyl)-benzaldehyde.

Methyl triphenylphosphonium iodide (7.5 mmol, 1.5 equiv) was dissolved in dry diethyl ether (50.0 mL) in a 100 mL round-bottom flask at 0 °C under dry nitrogen. Potassium *tert*-butoxide (10.0 mmol, 2 equiv) was added in one portion, and the mixture was stirred for 10 min. The crude product of aldehyde was added in one portion at 0 °C, and the reaction mixture was stirred for 24 h at rt. The mixture was added to a saturated aqueous NaCl solution (100 mL) and extracted with diethyl ether (3 × 20 mL). The combined organic extracts were dried over anhydrous MgSO₄ and evaporated under reduced pressure. The crude product was purified by chromatography on silica gel to afford desired styrene 1.

General Procedure for the Selective Synthesis of *E*-Trifluoromethylated Alkenes. A 25 mL Schlenk flask equipped with a rubber septum and a magnetic stir bar was charged with Ru(bpy)₃Cl₂·6H₂O (7.5 mg, 0.01 mmol, 2 mol %), 1 (0.5 mmol, 1.0 equiv), 2a (198.1 mg, 1.2 equiv, 0.6 mmol), and DMF (10.0 mL) under a nitrogen atmosphere. The mixture was degassed three times by the freeze-pump-thaw procedure. Then, the vial was placed 2 cm from blue LEDs. The mixture was stirred under a nitrogen atmosphere and irradiated by blue LEDs for 20 h. After the reaction was complete, the reaction mixture was diluted with water. The resulting mixture was extracted with diethyl ether, and the combined organic phase was washed with brine and then dried with magnesium sulfate. The solvent was removed under vacuum, and the crude product was purified by column chromatography to give *E* product 4.

General Procedure for the Selective Synthesis of Z-Trifluoromethylated Alkenes. A 25 mL Schlenk flask equipped with a rubber septum and a magnetic stir bar was charged with $Ir(ppy)_3$ (9.8 mg, 0.015 mmol, 3 mol %), 1 (0.5 mmol, 1.0 equiv), 2c (204.0 mg, 0.6 mmol, 1.2 equiv), and DMA (10.0 mL) under a nitrogen atmosphere. The mixture was degassed three times by the freeze-pump-thaw procedure. Then, the vial was placed 2 cm from blue LEDs. The mixture was stirred under a nitrogen atmosphere and irradiated by blue LEDs for 10 h. After the reaction was complete, the reaction mixture was diluted with water. The resulting mixture was extracted with diethyl ether, and the combined organic phase was washed with brine and then dried with magnesium sulfate. The solvent was removed under vacuum, and the crude product was purified by column chromatography to give Z product 5.

Trifluoromethylation of Steroid 1t. A 25 mL Schlenk flask equipped with a rubber septum and a magnetic stir bar was charged with $Ir(ppy)_3$ (3.9 mg, 0.006 mmol, 3 mol %), **It** (95.7 mg, 0.2 mmol, 1.0 equiv), **2c** (81.6 mg, 0.24 mmol, 1.2 equiv), and DMA (4.0 mL) under a nitrogen atmosphere. The mixture was degassed three times by the freeze-pump-thaw procedure. Then, the vial was placed 2 cm from blue LEDs. The mixture was stirred under a nitrogen atmosphere and irradiated by blue LEDs for 10 h. After the reaction was complete, the reaction mixture was diluted with water. The resulting mixture was extracted with diethyl ether, and the combined organic phase was washed with brine and then dried with magnesium sulfate. The solvent was removed under vacuum, and the crude product was purified by

column chromatography (silica gel, *n*-hexane/DCM = 10:1, then 5:1) to give products 4t (34.1 mg, 31%) and 5t (58.4 mg, 53%).

1-Pentafluoroethyl-1,3-dihydro-3,3-dimethyl-1,2-benziodoxole (2e). A two-necked, 50 mL round-bottom flask equipped with a massive magnetic stirring bar was charged with anhydrous spraydried potassium fluoride (464.8 mg, 8.0 mmol, 1.6 equiv) and flamedried with vigorous stirring under high vacuum for 5 min. Then, 1chloro-3,3-dimethyl-1,2-benziodoxole (1.48 g, 5.0 mmol, 1 equiv) followed by anhydrous MeCN (20 mL) was added. The resulting suspension was vigorously stirred for 12 h and then cooled to -10 °C, and pentafluoroethyltrimethylsilane (1.15 g, 6.0 mmol, 1.2 equiv) was injected in one portion. This resulting suspension was stirred vigorously for 1 h, allowed to warm to rt, and filtered over a 1 cm thick pad of Celite, and the filter cake was washed with a little MeCN. The brown solution was concentrated to dryness in a rotavap. The crystalline, crude residue was redissolved in dry n-pentane (30 mL) at rt, filtered over a pad of activated alumina, and covered by a protective compressed Celite layer into another two-necked, round-bottom flask equipped with a magnetic stirring bar. The filtrate was evaporated by slowly cooling it with stirring under Ar to -78 °C, causing the full precipitation of desired product 2e (493.7 mg, 26%) as a white solid (mp 121–124 °C). ¹H NMR (400 MHz, CDCl₃): δ 7.82 (d, J = 8.4Hz, 1H), 7.51 (t, J = 7.8 Hz, 1H), 7.47 (t, J = 7.2 Hz, 1H), 7.23 (d, J = 7.6 Hz, 1H), 1.49 (s, 6H). ¹³C NMR (100 MHz, CDCl₃): δ 149.6, 130.0, 130.9-128.6 (m), 129.4, 128.5-126.1 (m), 126.8, 126.4, 115.4, 80.3, 29.9. ¹⁹F NMR (376 MHz, CDCl₃): δ -81.3 (s, 3F), -99.3 (s, 2F). The residue was dissolved in DMF (2 mL), and CsF (91.2 mg, 0.6 mmol, 3.0 equiv) was added. The reaction mixture was heated at 150 °C for 3 h and then diluted with water. The resulting mixture was extracted with diethyl ether, and the combined organic phase was washed with brine and then dried with magnesium sulfate. The solvent was removed under vacuum, and the crude product was purified by column chromatography (silica gel, npentane) to give 8 (24.4 mg, 64%) as a colorless liquid. ¹H NMR (400 MHz, $CDCl_3$): δ 7.46 (t, J = 7.4 Hz, 1H), 7.39–7.33 (m, 1H), 7.29– 7.25 (m, 1H), 7.17 (t, J = 7.6 Hz, 1H), 7.13–7.08 (m, 1H), 6.34 (dq, J = 16.0, 6.4 Hz, 1H). ¹³C NMR (100 MHz, CDCl₃): δ 161.1 (d, J = 250.9 Hz), 131.5 (d, J = 8.7 Hz), 130.7 (qd, J = 7.3, 2.9 Hz), 128.8 (d, J = 2.9 Hz), 124.5 (d, J = 3.7 Hz), 123.4 (q, J = 267.6 Hz), 121.4 (d, J = 11.7 Hz), 118.5 (qd, J = 33.5, 7.3 Hz), 116.2 (d, J = 21.2 Hz). ¹⁹F NMR (376 MHz, CDCl₃): δ -63.9 (d, J = 6.8 Hz, 3F), -115.3 (m, J = 7.2 Hz, 1F). IR (thin film) ν_{max} : 2913, 2844, 1734, 1461, 1073 cm⁻¹. EIMS *m*/*z*: M⁺ 190 (100), 140 (43.1), 101 (21.4). HRMS-EI: calcd for C₉H₆F₄, 190.0406; found, 190.0408.
