Received 22 April 1999; accepted 13 May 1999

Abstract: On the basis of a systematic SAR analysis of substituted quinolines, a derivative 32 was synthesized that shows half-maximal inhibition of the immunostimulatory effect of CpG-oligodeoxynucleotides in vitro at the concentration of 0.24 nM. © 1999 Elsevier Science Ltd. All rights reserved.

Bacterial DNA, oligodeoxynucleotides, and phosphorothioate oligodeoxynucleotides with CpG-motifs (CpG-ODN) are immunostimulatory by an unknown mechanism.¹ Chloroquine (structure in Table 1) and its structural analogs including quinacrine inhibit the immunostimulatory effect at nanomolar concentrations in a test system that quantifies the ability of the compounds to block an effect of CpG-ODN on WEHI 321 murine B-cells (inhibition of growth arrest induced by engagement of surface immunoglobulin).¹ Evidence has been accumulating that this in vitro assay may provide the basis for a search for drug candidates for treating rheumatoid arthritis and systemic lupus erythematosus. For example, a number of quinoline derivatives that are active in this in vitro assay have also been shown to induce remission of rheumatoid arthritis and lupus erythematosus.^{2,3}

In this report we present for the first time a detailed SAR analysis of quinoline antagonists of immunostimulatory CpG-ODN's. The structures of compounds 1-32 are shown in Tables 1-5. The synthesis work together with SAR analysis of the synthesized quinolines culminated in the finding of an extremely active agent 32. We also comment on a possible mechanism.

Substituted quinolines $1,^4 3,^4 4,^5 6^6$ (Table 1), $7,^4 9,^4 10^4$ (Table 2), and 25^7 (Table 4) were available from other studies. Compounds 2 and 5 were obtained by using a general procedure.⁸ Compounds 11 and 14 (Table 3) were obtained by treatment of 4-chloroquinoline with the corresponding amine.⁷ An efficient synthesis of 2-aryl-4-chloroquinolines has recently been reported.⁷ These compounds served as substrates for 8, 12, 13, 15, and 16, 20–24, and 26–32 (Table 5). This chemistry is illustrated in Scheme 1 for the preparation of 28 by the reaction of 4-chloro-2-naphthylquinoline with 4-hydroxyaniline. A subsequent Mannich reaction of 28 with formaldehyde and N-methylpiperazine furnished 32. Compounds 29–31 were prepared in a similar manner. Finally, the quaternary compounds 17–19 (Table 3) were synthesized by the reaction of the corresponding aminoquinolines with MeI in DMF. The initially formed iodide of 17 [15 (0.12 mmol), MeI (0.10 mmol), Na₂CO₃ (0.24 mmol), DMF (2 mL), stirring at 23 °C for 12 h] resisted all attempts of crystallization. A bromide/

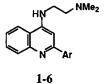

(i): p-H₂NC₆H₄OH (3 equiv), 130 °C, 4 h, then silica gel chromatography (Et₂O); (ii): **28** (1 mmol), *N*-methylpiperazine (5 mmol), aq CH₂O (13 M, 5 mmol), EtOH (20 mL), reflux, 24 h; then silica gel chromatography (AcOEt/Et₃N, 3/2).

hydrobromide derivative of 17 crystallized following treatment of a solution of the iodide in MeOH with HBr (48%, 3 mmol). Dibromides 18 and 19 were prepared in a similar way by the reaction of the respective quinolines 15 and 14 (0.12 mmol) with MeI (2 mmol) followed by treatment with HBr. Solid quinolines were purified by crystallization, and oily derivatives were transformed into solid salts by using a general procedure⁵ and the salts were crystallized. All compounds gave satisfactory results of elemental analysis and their structures were fully consistent with ¹H and ¹³C NMR data.⁹

The SAR studies were initiated following our finding that a 2-(2-naphthyl)quinoline 1 is more active than chloroquine and 2-phenylchloroquine (Table 1). It was of interest, therefore, to analyze analogs of 1 containing different groups at position 2 of the quinoline. In comparison to 1, the activity remains unchanged for 2, which contains a larger 3-phenanthryl group and is slightly decreased for the 1-naphthyl derivative 3 with a severe steric hindrance around the inter-ring bond. Interesting results are the high efficacy of quinoline 4 that is substituted with a relatively small *para*-tolyl group and an even greater activity for compound 5, which contains a styryl moiety. Comparison of compounds 4 and 6 reveals that the electron-withdrawing trifluoromethyl group in 6 exerts a strongly negative effect on the activity.

^aTaken from ref 1. Compounds 1–6 were assayed under the same conditions. The EC₅₀ is the concentration required for half-maximal inhibition of CpG-ODN effect on thymidine uptake by WEHI 231 B-cells in the presence of α -sIgM. The estimated experimental error is $\pm 15\%$.

The effect of basicity of the ring nitrogen atom in selected quinolines 1 and 7–10 was investigated (Table 2). As discussed previously,⁴ the given pK_a values are functions of electronic effects of the 4-substituent at the quinoline including inhibition of the conjugation effect in 7 due to steric hindrance. As can be seen from Table 2, the pK_a values of 1, 7–10 parallel nicely the respective EC₅₀ values.

 Table 2.
 The Experimental pKa Values of Quinolines 1, 7–10^a and Their Activity

^aThe values for 1, 7, 9, and 10 are taken from ref. 4.

Further analogs of 1 are analyzed in Table 3. These are quinolines with and without aryl substitution, with an increasing length of the (dimethylamino)polymethylene chain, and several quaternized derivatives in which a positive charge is permanently fixed. There is a dramatic increase in activity, due to 2-aryl substitution, as can be seen from comparison of 11 to 12 and 13 and comparison of 14 to 15. On the other hand, the activities of compounds 4 and 1 containing the same (dimethylamino)dimethylene side chain are similar to those of the respective (dimethylamino)trimethylene analogs 12 and 13. As the chain length increases in the series of compounds 13, 15, and 16, which contain the same 2-(2-naphthyl)quinolin-4-amine core, the activity reaches a maximum for a tetramethylene derivative 15 and then is slightly decreased for compound 16 which has a hexamethyl-

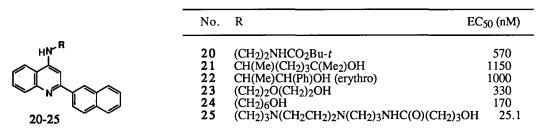

Table 3. Activities of Quinolin-4-amines 11–18 and Quaternary Derivatives 17–19

ene linker. To our surprise, methylation of the terminal dimethylamino group of 15 rendered the resultant trimethylammonium derivative 17 completely inactive. An additional methylation of 17 at the ring nitrogen atom restored some activity in the resultant dication 18. However, a dication 19 devoid of the naphthyl group was completely inactive again. Our additional studies (not shown) consistently indicated that compound 1 and its numerous analogs with a severely sterically hindered amino function at the terminus of the side chain showed comparable activities. Accordingly, the lack of activity of 17 and 19 cannot be explained in terms of an increased bulkiness of the trimethylammonium substituent in comparison to that of the dimethylamino group.

Analogs of 1 containing an alkyl group at N4 of the quinoline were inactive as well (not shown; see, however, **26** in Table 5). On the other hand, quinolines that contain groups capable of a hydrogen bonding interaction, such as a urethane in **20** or a hydroxy group in **21–24** (Table 4) show some activity. The activity of **25**, the side chain of which contains additional amino functions, is greater.

This activity pattern is retained in a series of substituted 4-anilinoquinolines 26–32 (Table 5). Compound 32 has a relatively basic quinoline ($pK_a = 6.9$, a calculated value), contains hydroxy and amino functions, and is the most potent antagonist of immunostimulatory CpG-ODN's found to date.

In order to better understand the requirements for activity, eleven 2-(2-naphthyl)quinolin-4-amines of Tables 4 and 5, all containing a hydroxy group at the side chain and occasionally substituted with additional amino groups, were subjected to correlation analysis by using calculated connectivity indices. These parameters, depending on their order, encode the length and the size of a substituent and also the type and position of branching. The lipophilicity, length, and branching of hydrocarbon substituents are well characterized by the set of ${}^{3}X_{p}^{v}$ indices.¹⁰

A statistically significant QSAR correlation for the eleven substituents, all containing free (non-protonated) amino groups at the side chain, was obtained (eq 1).

$$log (1/EC_{50}) = 0.534 (\pm 0.08) {}^{3}X_{p}{}^{v} + 5.600 (\pm 0.27)$$
(1)
n = 11 (C4 groups of **21-25** and **27-32**), r = 0.934, s = 0.49, F_{0.01} = 61.09

A slightly inferior correlation was obtained for the same set of substituents with protonated amino groups excepting the N4 atom at the quinoline which is non-basic due to the strong conjugation effect (not shown).

However, surprising as it may seem, these results and the experimental results obtained with quaternary compounds 17-19 suggest that the basic amino group (pK_a > 8) at the side chain of an active agent is not protonated in the compound-bioreceptor complex. On the other hand, the observed pK_a correlation (Table 2) and the activity of the N1-quaternized quinoline 18^{11} are consistent with protonation of the relatively less basic ring nitrogen (pK_a < 8). It can be suggested that the free amino group is located in a lipophilic microenvironment of the bioactive complex and is involved in hydrogen-bonding interaction with a hydrogen donor of the receptor. This hypothesis is consistent with our finding that hydroxy-substituted derivatives also show some activity. Proteins or phospholipids are likely candidates as the bioreceptor.

Since nucleic acids are involved and several compounds of this study have been shown previously to strongly stabilize a triple-helix DNA structure, it was hypothesized initially that stabilization of the triple helix complex is part of the mechanism. However, while the isomeric compounds 1 and 3 are antagonists of the CpG-induced effect and compound 1 is one of the best triplex DNA stabilizing agents known to date, the sterically hindered isomer 3 does not promote triplex DNA formation and does not bind to the triple DNA structure.⁴ While compound 1 binds weakly to duplex DNA, compound 3 does not bind at all. The two compounds do not stabilize a quadruplex DNA as well. In addition, compound 1 binds weakly to RNA.¹² Thus, it can be suggested that the mechanism of quinoline antagonists does not involve binding to CpG-ODN.

4-Quinolinamines which inhibit CpG-ODN-induced effects are weak bases. Weak bases tend to partition into acidified vesicles within cells.¹³ Chloroquine has been well studied in this regard. It concentrates in lysosomes and collapses the pH gradient,¹⁴ leading to the hypothesis that organelle acidification is required for intracellular recognition of CpG-ODN.¹⁵ However, this hypothesis is not consistent with the activity of a diquaternary derivative **18** which is not a base. In addition, a number of independent experiments consistently indicated that the active compounds do not inhibit the action of CpG-ODN by interfering with the acidification of vesicles, nor with the uptake or subcellular distribution of CpG-ODN (D.E. Macfarlane, manuscript in preparation). In summary, it seems most likely that these agents inhibit the detector system for CpG-ODN by a specific mechanism, not by a bulk effect.
