Transition metal imido complexes have risen to prominence among metal-ligand multiply bonded systems because of the diverse range of chemistry in which they participate. One standard strategy for the synthesis of arylimido complexes is the reaction of an organic azide with a metal complex capable of undergoing 2e oxidation. Although organoazide complexes have been proposed as intermediates prior to dinitrogen evolution,² it appears that none have previously been isolated and fully characterized. Herein we report the isolation and structural characterization of an unusually stable terminal mesityl azide complex, $V(N_3Mes)(I)(NRAr_F)_2$ (1; $R = C(CD_3)_2CH_3$, $Ar_F =$ $2.5-C_6H_3FMe$, Mes = $2.4.6-C_6H_2Me_3$), in which the aryl azide moiety is best described as a "diazenylimido" ligand. The synthesis of 1 is presented along with preliminary mechanistic information regarding its conversion to the imido complex $V(NMes)(I)(NRAr_F)_2$ (2) at 54 °C.

The vanadium(III) complex V(I)(NRAr_F)₂ (3) was synthesized in three steps (Scheme 1). Slow addition of a THF solution of Li(NRAr_F)(OEt₂)³ (7.484 mmol, 0.05 M) to a THF slurry of VCl₃(THF)₃ (3.743 mmol) led to the isolation of V(THF)(Cl)-(NRAr_F)₂ (4) in 65% yield.⁴ The THF-free species V(Cl)-(NRAr_F)₂ (5) was obtained as a forest green crystalline solid in 92% yield by trituration with toluene.⁵ V(Cl)(NRAr_F)₂ (5) exhibits a $\mu_{\rm eff}$ of 2.60 $\mu_{\rm B}$ in benzene- d_6 , suggesting that the complex is probably not exclusively monomeric in hydrocarbon solvents.6 For this reason, and because of the relatively low solubility of 5, the chloride was replaced with iodide. A solution of ISiMe₃ (434 μ L, 3.05 mmol) in ether was added to a stirred slurry of 5 (1.3697 g, 2.985 mmol) in 50 mL of cold (≈-100 °C) ether, leading to the isolation of V(I)(NRAr_F)₂ (3) in 88% yield after warming to 30 °C and recrystallization (pentane, -35 °C). Dark brown crystalline 3 has good solubility in hydrocarbon solvents and a μ_{eff} of 3.01 μ_{B} .

A dark, yellow-brown solution of V(I)(NRAr_F)₂ (3, 2.1793 mmol) in ether was cooled to ca. -100 °C, whereupon it turned

emerald green.⁸ Dropwise addition of mesityl azide (2.231 mmol) as a 0.750 M solution in ether resulted in an immediate color change to reddish brown. After the magnetically-stirred reaction mixture had warmed to 30 °C, it was cooled to -35 °C to provide crystalline 1 in 79% isolated yield (three crops).9 Because 1 was found to be diamagnetic, yet possessed ¹H, ¹³C, ¹⁹F, and ⁵¹V NMR spectra completely different from those of imido 2 (see below), the structure of 1 was determined by X-ray diffraction.10

The structure of $V(N_3Mes)(I)(NRAr_F)_2$ (1; Figure 1) is readily interpreted in terms of 2e reduction of the aryl azide concomitant with complexation of its terminal nitrogen atom. The complexed MesN₃ unit is best described as a "diazenylimido" ligand in that the V-N(1) distance for 1 (1.662(4) Å) is nearly as short as the corresponding distance (1.645(7) Å) for imido 2. A pseudo-triple bond between V and N(1) is thereby indicated.¹¹ The nearly linear V-N(1)-N(2) angle for 1 (169.1(4)°) also compares well with the V-N-C angle (175.7(7)°) for 2. A double bond between N(2) and N(3) is indicated by their 1.198-(6) Å separation, which is slightly shorter than the corresponding distance (1.243(3) Å) in trans-azobenzene. 12 As is typical for aryl azo compounds, the mesityl ring in 1 is essentially coplanar with the plane defined by nitrogens 1, 2, and $3.^{13}$

(8) Although the origin of this thermochromism is not yet clear, it may correlate with a reversible structural change. On cooling ether solutions of 3 to -85 °C we observe near-complete replacement of the ²H NMR signal at 21.1 ppm by a new signal at 25.2 ppm. The color change to emerald green cannot be attributed solely to solvent coordination, since Pentane solutions of 3 exhibit the same phenomenon upon cooling. Variable-temperature UV—vis experiments designed to further elucidate the

Variable-temperature UV—vis experiments designed to further elucidate the thermochromic behavior of 3 are underway. Although "diazenylimido" 1 is formally related to Staudinger phosphazides (R₃PNNNAr), it differs from them both structurally and in the kinetics of its N₂ extrusion upon heating. Structurally, phosphazides are found to be bent $(115 \pm 5^{\circ})$ rather than linear at N(1), and the π -system is more delocalized in phosphazides than in 1.¹⁴ Mechanistic studies have shown that phosphazides may eliminate N₂ in a unimolecular fashion, for which a cyclic transition state has been postulated.¹⁴ In contrast, the $1 \rightarrow 2$ conversion with N₂ extrusion follows second-order kinetics at 54 °C.¹⁵ This contrasts sharply with the observation, by Proulx and Bergman, that Cp₂Ta(N₃Ph)(CH₃) loses dinitrogen in a first-order manner.¹⁶ A double-labeling experiment, in which equal amounts of V(N₃Ar)(I)(N[C(CH₃)₃]Ar_F)₂ (6, Ar = 2,6-C₆H₃Me₂)¹⁷ and 1 were thermolyzed together (50 °C, 6 h,

(16) Proulx, G.; Bergman, R. G. J. Am. Chem. Soc. 1995, 117, 6382-6383.

4.2 mM in each component), gave clear evidence of crossover. ¹⁸ While our preliminary kinetic and labeling results are intriguing, more data are required in order to draw a firm conclusion regarding the mechanism of N_2 extrusion from 1. ¹⁹

The imido complex V(NMes)(I)(NRAr_F)₂ (2, Scheme 1) was also prepared directly by dropwise addition of mesityl azide (91.3 mg, 566 μ mol) to a magnetically stirred solution of 3 $(0.299 \text{ g}, 543 \mu\text{mol})$ in ether at 30 °C. The reaction mixture quickly became dark red, and effervescence was observed over 5 min. Removal of all volatile material, followed by extraction with pentane and cooling to -35 °C, gave diamagnetic 2 in 89% yield as dark red crystals.²⁰ ¹H NMR spectra of 2 are consistent with the presence of two isomers in a 6:1 ratio.²¹ It is intriguing that treatment of 3 with MesN₃ at 30 °C gives imido 2 directly, since purified 1 is relatively stable at that temperature. Control experiments show that 3 is not a competent catalyst for N₂ extrusion from 1 at 30 °C, but it is possible that a trace catalyst for the $1 \rightarrow 2$ conversion is generated in situ in the 30 experiment. It is also possible that "diazenylimido" 1 is not an intermediate in the synthesis of imido 2 at 30 °C.²²

In summary, we have established the structure of a rare organoazide complex of vanadium and have begun to delineate the conditions under which it extrudes dinitrogen to provide a structurally similar arylimido derivative. Future work will concentrate on the mechanism of N_2 extrusion from 1 and on other possible modes of reaction for this complex.
