SYNTHESIS OF A BRANCHED LOCKED NUCLEIC ACID (LNA) ANALOGUE

Pawan K. Sharma Department of Chemistry, Kurukshetra University, Kurukshetra, India

Surender Kumar Department of Chemistry, Kurukshetra University, Kurukshetra, India and Nucleic Acid Center, Department of Physics and Chemistry, University of Southern Denmark, Odense M, Denmark

Poul Nielsen Ducleic Acid Center, Department of Physics and Chemistry, University of Southern Denmark, Odense M, Denmark

 \Box A 3'-C-branched LNA-type bicyclic nucleoside, containing a furanose ring locked in an N-type conformation, was synthesized from a known 3-C-vinyl allofuranose derivative using a strategy relying on the condensation with the nucleobase after the introduction of the branching hydroxymethyl chain by our recently developed RuO₄ based protocol. This branched LNA nucleoside has a potential as a monomer for the functionalization of LNA.

Keywords Locked nucleic acid; N-type conformation; RuO₄ oxidation

In nucleic acid chemistry, conformationally restricted nucleoside building blocks are powerful tools for the design of oligodeoxynucleotides (ODNs) with selective and high-affinity recognition of complementary nucleic acids. Furthermore, the structural control embedded by these building blocks opens for the design of functional nucleic acid architectures.^[1] Locked nucleic acid (LNA) represents the most absorbing example in which the conformation of the furanose moiety is locked in an N-type (C3'*endo*) conformation (Figure 1).^[2] The incorporation of one or more LNA monomers into an ODN strongly increases the thermal stability of the duplex formed with single-stranded DNA or RNA complements.^[2] LNA has

been shown to be very useful for antisense applications,^[3] and amino-LNA has been used for the preparation of functionalized nucleic acids.^[4]

3'-C-Branched nucleoside building blocks have been made to improve either enzymatic stability of the ODN or the binding affinity toward complementary targets (Figure 1).^[5] In general, ODNs with 3'-Cbranched nucleotides exhibit slightly decreased hybridization properties and improved stability against 3'-exonucleases. Furthermore, they contain branching points which can be used as conjugation sites for a variety of functional moieties such as peptides or other nucleotides.^[5] A 3'-substituent is expected to be oriented in a pseudoequatorial position, driving the sugar pucker towards a C-2'-endo conformation, thus explaining why the binding affinity toward RNA is somewhat impaired.^[5] On the other hand, the 3'-Calkyl substituents (including the 3'-C-hydroxymethyl substituent) point into the major groove of DNA:DNA and DNA:RNA duplexes and are reasonably well tolerated in the duplex structure.^[5] Therefore, it was appealing to study this structural feature in the context of an LNA monomer, in which the locked N-type conformation forces the 3'-hydroxymethyl group into an axial position. Longer alkyl groups in the same position have been studied before leading to some decrease in thermal stability.^[6] However, we envisioned the smaller 3'-hydroxymethyl group to be better accommodated into duplexes.

For the introduction of the hydroxymethyl branch at the β -face of C3' of a nucleoside, a convergent synthesis strategy starting from 1,2:5,6-di-*O*-isopropylidene- α -D-glucofuranose 1 was chosen, and the known 3-*C*-vinyl derivative $2^{[7]}$ was prepared in three steps. In our first strategy, this compound was efficiently converted into a 3'-hydroxymethyl derivative by our recently developed ruthenium protocol for oxidative cleavage.^[8] However, all attempt of making a successful preparation of the target nucleoside from this strategy failed due to problems with the 3'-hydroxymethyl moiety in the

subsequent steps. Therefore, we decided to apply a second strategy in which the vinyl group is cleaved later, and **2** was eventually converted to **3** through oxidative cleavage of the C5–C6 bond and an aldol condensation. Selective protection followed by the ruthenium based oxidative cleavage^[8] and a new benzylation afforded **4**. Adapted standard conversions gave the nucleoside **5**. A deprotection, a selective mesylation, ring-closure and a debenzylation afforded the target nucleoside **6**. Efforts towards the incorporation of **6** into functionalised ODNs are in progress.
