### ABSTRACT

3-Amino-3-deoxy-2,4,5,6-tetra-*O*-methyl-D-altronic acid hydrochloride was the key intermediate in the preparation of poly[(2*S*,3*R*)-2-methoxy-3-(*D*-erythro-trimethoxypropyl)propanamide], a chiral nylon 3 analog. We now describe an alternative synthetic route to this amino acid and the unexpected reactivity of some of its 3-deoxy derivatives. Attempts to open the 3-azido-3-deoxy-tri-*O*-methyl (or *O*-benzyl)-D-altrono-1,5-lactone intermediates gave mixtures of products, mostly,  $\alpha,\beta$ -unsaturated carbonyl compounds.

### INTRODUCTION

Poly( $\beta$ -peptide)s, which can be envisaged as nylon 3 derivatives, are able to adopt regular folded structures stabilized by intramolecular hydrogen bonds with features very similar to the  $\alpha$ -helix characteristic of poly( $\alpha$ -peptide)s. Recently, it has been demonstrated<sup>1–3</sup> that not only main chain substitution but also the constitution and position of the substituents are determinant for the conformation adopted by poly( $\beta$ -peptide)s and more specifically for the type of helix that they may form. On the other hand, synthetic polymers containing carbohydrate units in

the main chain are considered as a new type of polymeric material<sup>4</sup> due to their potential as biodegradable and biocompatible materials useful for medical applications.

We have recently described the preparation of 3-amino-3-deoxy-2,4,5,6-tetra-*O*-methyl-D-altronic acid hydrochloride (**2**) through the 3-acetamido-3-deoxy-2,4,6-tri-*O*-methyl-D-altrono-1,5-lactone (**1**)<sup>5</sup>. This aminoaldonic acid was transformed into the corresponding  $\beta$ -lactam, (3*S*,4*R*)-3-methoxy-4-(*D*-erythro-trimethoxypropyl)azetidine-2-one (**3**), which was further polymerized by anionic ring-opening polymerization to give poly[(2*S*,3*R*)-2-methoxy-3-(*D*-erythro-trimethoxypropyl)propanamide] (**4**), a chiral nylon 3 analog (Scheme 1)<sup>5</sup>. Due to increasing interest in enantiomerically pure  $\beta$ -amino acids, we tried some alternative approaches to the preparation of *O*-benzyl and *O*-methyl derivatives of the 3-amino-3-deoxy-D-altronic acid. Thus, we attempted to prepare the aminoaldonic acid **2** by opening the lactone ring of 3-azido-3-deoxy-2,4,6-tri-*O*-methyl-D-altrono-1,5-lactone (**13**) which is a precursor of **1**, but complex mixtures of products, mainly  $\alpha,\beta$ -unsaturated carbonyl compounds, were formed. Likewise, the 3-azido-3-deoxy-2,4,6-tri-*O*-benzyl-D-altrono-1,5-lactone (**10**) behaved in a similar way. We now describe an alternative synthetic route to the amino acid **2**, the preparation of lactones **10** and **13** and some other derivatives, and some results on their chemical reactivity.

## RESULTS AND DISCUSSION

Per-*O*-benzylation of **5** to obtain **6** (Scheme 2) was carried out with benzyl bromide in the presence of sodium hydride in DMF (92%). The *O*-methyl group of **6** was hydrolyzed with 4M hydrochloric acid in acetonitrile at 85°C, and the tri-*O*-

benzyl derivative **8** was obtained in a 75% yield. Oxidation of **8** with pyridinium chlorochromate (PCC) in dichloromethane afforded a good yield (56%) of the corresponding 3-azido-3-deoxy-tri-*O*-benzyl-1,5-D-altrono-lactone (**10**). However, attempts to oxidize **8** with dimethyl sulfoxide-acetic anhydride (1:1) gave rise to a complex mixture of products, from which 6% of the  $\alpha,\beta$ -unsaturated lactone **9** could be isolated. The latter compound could have been formed by  $\beta$ -elimination of the azido group from the preformed lactone **10**.

In a similar way, PCC oxidation of **12** gave the lactone **13** (Scheme 3). Opening of lactones **10** and **13** with methyl iodide as described previously<sup>5-7</sup> was unsuccessful. Under those conditions very complex mixture of products were formed, most of them showing (TLC) intense absorbance under UV light which, together with the NMR data, indicated the presence of conjugated unsaturated systems.

We could verify that these compounds, having a  $\beta$ -azido carbonyl system, suffered  $\beta$ -elimination of the azido group under basic conditions, even with bases as weak as triethylamine. The driving force for this process could be the high stability of the  $\alpha,\beta$ -unsaturated carbonyl system and the favorable entropic factor. The  $\beta$ -elimination of benzoate and benzyl groups from 1,5-aldonolactones<sup>8,9</sup> and 1,5-aldonolactams<sup>10</sup> respectively, had been reported to give the corresponding  $\alpha,\beta$ -unsaturated derivatives. Earlier studies from our laboratory also described<sup>11</sup> the  $\beta$ -elimination of the methoxy group at C-3 of 2,3,4-tri-*O*-methyl-D-xylono (and L-arabinono)-1,5-lactones.

We also undertook the opening of lactone **13** under acidic conditions (Scheme 3). Its reaction with camphorsulfonic acid in dry methanol at room temperature for 7 h, afforded **14** in 94% yield, whereas reaction of **13** with methyl orthoformate in methanol, in the presence of sulfuric acid at 50°C, afforded only a 35% yield of **14**. When trifluoromethanesulfonic acid was used instead of sulfuric acid, **14** was isolated in 59% yield.

Scheme 2.

We tried the methylation of OH-5 of **14** by several different methods. Compound **14** was recovered unaltered after treatment with diazomethane in diethyl ether in the presence of silica gel for 6 days, whereas when **14** was treated with sodium hydride/methyl iodide in dry DMF,  $\beta$ -elimination reactions took place, and unsaturated compounds **15** and **17–19** were isolated in 20%, 18%, 33% and 28% yields, respectively. However, treatment of **14** with methyl iodide and silver oxide under different conditions gave the desired product **16** in moderate to low yields. Most of these experiments produced **16** along with lactone **13**,  $\alpha,\beta$ -unsaturated lactone **15** and, in some cases, other unsaturated compounds. The reduction of the azido group at C-3 of **16** took place easily with hydrogen and 10% Pd/C, and the intermediate methyl 3-amino-3-deoxy-2,4,5,6-tetra-*O*-methyl-D-altronate was hydrolyzed with 4M hydrochloric acid to give 3-amino-3-deoxy-2,4,5,6-tetra-*O*-methyl-D-altronic acid hydrochloride (**2**).

In order to prevent elimination reactions, the azido groups of **6** and **11** were reduced with hydrogen in the presence of 10% Pd/C in methanol, and the amino compounds **7** and **20** were obtained in good yields. Hydrolysis of the methyl glycoside **20** (Scheme 4) with 4M hydrochloric acid-acetonitrile gave **21** in 85% yield, and the amino group was protected as *N*-benzyloxycarbonyl derivative to give **22**. Oxidation of **22** with PCC in dichloromethane yielded lactone **23** (87%). However, treatment of **23** with methyl iodide, under the conditions known<sup>5–7</sup> to open the

lactone ring with methylation of OH-5, gave the cyclic urethane **24** (60%). The formation of **24** could be explained as nucleophilic attack by the free OH-5, of the corresponding open chain derivative, on the carbonyl of the *N*-protecting group, with displacement of the benzyloxy group.

In conclusion, due to the easy elimination of the azido group at C-3 of lactone **13**, attempts to open the lactone ring under basic conditions did not give good yields of **16**, the precursor of the amino acid **2**, but mixtures of  $\alpha,\beta$ -unsaturated carbonyl compounds were obtained instead. However, compound **16** was obtained in low to moderate yield, in two steps, by treatment of **13** with camphorsulfonic acid, then methylation of OH-5 of **14**, under mild conditions, with silver oxide and methyl iodide. Alternatively, as we have already described<sup>5</sup> the amino acid **2** was prepared from the acetamido lactone **1**. Lactones **13** and **1** were both easily obtained from **12**.

## EXPERIMENTAL

**General Methods.** Chemicals were all used as purchased from the Aldrich Chemical Co. Solvents were dried and purified, when necessary, by appropriate standard procedures. Melting points are uncorrected. Optical rotations were measured at  $20 \pm 5^\circ\text{C}$  with a Bellingham & Standley Inc., P20 polarimeter (5-cm cell). TLC was performed on Silica Gel 60 F<sub>254</sub> (Merck) with detection by UV light or charring with sulfuric acid and flash column chromatography with Silica Gel 60 (230–400 mesh, Merck). Elemental analyses were determined in the Microanalysis Laboratories at the Universidad Complutense de Madrid. FT IR spectra: films or KBr discs. NMR spectra: chemical shifts are reported as parts per million down field from tetramethylsilane. MS were recorded on a Kratos MS80RFA instrument

equipped with a combined EI-CI source. HRMS (EI, 70 eV) were taken with 10000.

(2). A solution of **16** (0.025 g, 0.086 mmol) in methanol (1 mL) was stirred with 10% Pd/C (3 mg) for 2 h under a hydrogen atmosphere. The suspension was filtered through diatomaceous earth and the solution concentrated to dryness. The residue was purified by flash-column chromatography (ethyl acetate) to give a compound (0.022 g, 97%) that was identified as methyl 3-amino-3-deoxy-2,4,5,6-tetra-*O*-methyl-D-altronate, according to the following data: IR 3420, 1630 (NH<sub>2</sub>), 1750 cm<sup>-1</sup> (CO ester); <sup>13</sup>C NMR (CDCl<sub>3</sub>, 50 MHz), δ 170.74 (C-1), 81.24, 78.23, 77.64 (C-2/C-4/C-5), 69.82 (C-6), 59.80, 59.16, 58.60, 57.65 (4 OCH<sub>3</sub>), 54.32 (C-3), 52.45 (COOCH<sub>3</sub>). The above compound was treated with 4M HCl (2 mL) at room temperature for 5 days, then concentrated. The residue was treated with light petroleum to give a solid which was identified as the previously described **2**<sup>5</sup> (0.024 g, 93%).
