

dates<sup>1</sup>. A mechanism consistent with the results obtained is shown in the following scheme.

As the dioxazoles **3** are key intermediates in the synthesis of many interesting compound types<sup>2</sup> we report now an improved preparative method which can be applied starting from all fully substituted 5-alkoxyoxazoles.

The reaction of **1a** with the singlet oxygen in the presence of concentrations of the same order of substrate and 1,4-diazabicyclo[2.2.2]octane (DABCO) is completely inhibited

**Table 1.** Effect of the DABCO Concentration on the Dye-sensitized Photooxidation of **1a**

Initial Conc. <sup>a</sup> × 10 <sup>3</sup> (molar) of <b>1a</b>	Oxidation [%]	Reaction Time <sup>b</sup> [h]	Yield <sup>c</sup> [%]

Recently we reported that 5-alkoxy-4-methyl-2-phenyloxazoles (**1a** and **1b**) are partly converted, by dye-sensitized photooxidation, into 3-alkoxycarbonyl-3-methyl-5-phenyl-1,2,4-dioxazoles (**3a** and **3b**) (yields 47%) which are the first examples of this ring system, and also the first peroxyimi-

according to the general pathway of the reactions involving the singlet oxygen<sup>3</sup>. However the yields of **3a** are remarkably improved (97%) when the reaction is carried out in the presence of small amounts of DABCO (Table 1).

is involved in this process remains to be resolved. It is part of the general inhibition mechanism by DABCO which is yet unknown<sup>4</sup>.

As shown in Table 2, the photooxidation in the presence of DABCO has a wide range of applicability even though attempts to synthesize 3-monosubstituted 3*H*-1,2,4-dioxazoles from 4-unsubstituted oxazoles failed.

#### Photosensitized Oxidation of Oxazoles 1 in the Presence of DABCO; General Procedure:

A solution of the oxazole (2 mmol), methylene blue ( $1.6 \times 10^{-2}$  mmol), and DABCO (0.18 mmol) in dry chloroform (20 ml) is irradiated with a halogen-superphot lamp (Osram 650 W). During the irradiation, dry oxygen is bubbled through the solution which is cooled with a water sleeve. When the reaction is complete (<sup>1</sup>H-N.M.R.), the solvent is removed in vacuo and the residue is filtered through a short column of silica gel [eluent: light petroleum/ether (9:1)]. Evaporation of the solvent gives the pure dioxazoles **3**.

Support of our work by the Italian C.N.R. is gratefully acknowledged.

<sup>a</sup> Molar ratio of oxazole **1**: DABCO = 11:1.

<sup>b</sup> Products are oils except for **3d** (m.p. 57–59°) and **3e** (m.p. 47–49°).

<sup>c</sup> Time required for reaction at room temperature.

<sup>d</sup> All new compounds gave satisfactory microanalyses (C ± 0.48%, H ± 0.24%, N ± 0.21%, O<sub>act</sub> ± 0.53); analyses were performed by Mikroanalytisches Laboratorium E. Thommen, CH-4126 Bettingen, Switzerland.

<sup>e</sup> Recorded on a Perkin Elmer R 12A spectrometer.

The above results can be rationalized assuming that the appropriate DABCO concentration suppresses the 1,4-addition of the singlet oxygen to the oxazole **1a**, but only retards the 1,2-addition. However, the manner in which the DABCO
