Received July 30, 1984

In the presence of catalytic amounts of aluminum bromide (or chloride), selective mono-, di-, tri-, or tetramethylation of germanium tetrachloride was effected in high yield with tetramethylsilane (Me<sub>4</sub>Si) as the methylating reagent. According to the Me<sub>4</sub>Si/GeCl<sub>4</sub> ratio, MeGeCl<sub>3</sub>, Me<sub>2</sub>GeCl<sub>2</sub>, Me<sub>3</sub>GeCl, and Me<sub>4</sub>Ge were prepared in 66, 86, 100, and 91% maximum yields, respectively. In these reactions, Me<sub>4</sub>Si was converted into Me<sub>3</sub>SiCl and subsequently Me<sub>2</sub>SiCl<sub>2</sub>. A mechanism for methylation is proposed, involving the initial formation of Me<sub>4</sub>Ge (observed regardless of the proportions of starting reagents) followed by disproportionation reactions, with methylchlorosilanes or -germanes present when the initial molecular ratio  $Me_4Si/GeCl_4$  was lower than 4/1.

## Introduction

During the course of the industrial preparation (direct synthesis) of  $Me_2SiCl_2$ ,  $Me_4Si$  is formed in about 0.5% by weight relative to Me<sub>2</sub>SiCl<sub>2</sub>. The potentially utilizable four methyl groups attached to silicon have made this a compound of interest in our laboratory.<sup>2-6</sup> Thus, in the context of numerous studies concerning the electrophilic reactivity of the Si-Me bonds of Me<sub>4</sub>Si, we have previously effected its conversion into Me<sub>3</sub>SiCl either by the reaction with chlorine in the presence of catalytic amounts of iodine<sup>3,4</sup> or with other chlorosilanes such as MeSiCl<sub>3</sub>, the main byproduct of direct synthesis,<sup>5</sup> or again with common polyhalo derivatives.<sup>6</sup> Moreover, some investigations in our laboratory were devoted to the use of Me<sub>4</sub>Si as a methylating or silylating reagent for sulfonic moieties.<sup>2</sup> The useful and commercially available sulfonation reagent ClSO<sub>3</sub>SiMe<sub>3</sub>, for instance, was obtained from ClSO<sub>3</sub>H and Me<sub>4</sub>Si.<sup>2</sup>

Methylchlorogermanes are important basic starting materials of organogermanium chemistry.<sup>7,8</sup> Consequently, we thought that Me<sub>4</sub>Si could provide a convenient entry to methylchlorogermanes by methylation of germanium tetrachloride. We were encouraged by the Me/Cl exchange observed by Burch and Van Wazer<sup>9</sup> between germanium compounds at 300 °C in the presence of 0.1%  $AlCl_3$  (eq 1-3).

> $Me_4Ge + GeCl_4 \rightleftharpoons Me_3GeCl + MeGeCl_3$ (1)

$$Me_3GeCl + MeGeCl_3 \rightleftharpoons 2Me_2GeCl_2$$
 (2)

$$Me_4Ge + MeGeCl_3 \rightleftharpoons Me_3GeCl + Me_2GeCl_2$$
 (3)

These disproportionation reactions, slow under these conditions (4-30 days<sup>9</sup>), allowed the synthesis of methylchlorogermanes from Me<sub>4</sub>Ge and GeCl<sub>4</sub> even at 200 °C.<sup>10</sup> However, this route used as  $Me_4Ge$  a methyl source, which is only available from MeMgX and  $GeCl_4$  (or  $(Me_3Ge)_2O$ , also obtained after previous methylation).<sup>8</sup>

Also, our proposed route seemed attractive to us in comparison to the other routes to alkylchlorogermanes.<sup>7,8,11</sup>  $R_3GeX$  and  $R_2GeX_2$  (R = Bu, X = Cl; R = Et, X = Br) had been obtained from  $R_4Ge$  and  $GeX_4$  in the presence of large amounts of  $AlCl_3$ .<sup>7,11</sup>  $R_3GeCl$  had been prepared previously from  $R_4Ge$  by R/Cl exchange with HCl, Me-COCl, or halo derivatives in the presence of AlCl<sub>3</sub> and with metal halides such as SbCl<sub>5</sub>, GaCl<sub>3</sub>, or SnCl<sub>4</sub>.<sup>8</sup> R<sub>3</sub>GeCl also was obtained from  $(R_3Ge)_2O$  and  $HCl^8$  or, by halogen exchange, from  $R_3GeX$  (X = Br, I) and AgCl<sup>8</sup> but  $R_2GeCl_2$ was not generally available from these methods since cleavage of a second R-Ge bond does not occur with HCl<sup>7</sup> and alkylation using organolithium or Grignard reagents generally affords a mixture of alkylchlorogermanes.<sup>7</sup> The direct synthesis of R<sub>2</sub>GeCl<sub>2</sub> by the Rochow method (RCl and Ge catalyzed by copper derivatives) occurs in good yields with R = Me and  $Et^{7,8}$  but is complicated by secondary reactions when larger alkyl halides are used.<sup>7,8</sup>

RGeCl<sub>3</sub> was previously difficult to obtain (as a byproduct in the direct synthesis of R<sub>2</sub>GeCl<sub>2</sub>,<sup>7,8</sup> by addition of HGeCl<sub>3</sub> to alkenes,<sup>7,8</sup> or by halogen exchange from  $RGeX_3$  (X = Br, I)).<sup>7,8</sup>

This survey of the literature encouraged us to investigate the Me/Cl exchange, starting from  $SiMe_4$  and  $GeCl_4$ .

### Results

Reactions were carried out on a scale of 50 mmol of GeCl<sub>4</sub> in an autoclave at temperatures over 180 °C, generally 200 °C, in the presence of 3-5 mol % of AlBr<sub>3</sub>. Organogermanium and silicon bromides were not detected in appreciable amounts after the reaction. Although  $AlCl_3$ in similar proportions gave similar results, we are reporting only attempts with AlBr<sub>3</sub> as it led to a much faster reaction, perhaps because of its good solubility in the medium. By a judicious choice of the ratio of Me<sub>4</sub>Si to GeCl<sub>4</sub> and a convenient reaction time, this versatile reaction provided selectively Me<sub>4</sub>Ge, Me<sub>3</sub>GeCl, Me<sub>2</sub>GeCl<sub>2</sub>, or MeGeCl<sub>3</sub> in high or quantitative yields.

<sup>a</sup> Determined by <sup>1</sup>H NMR spectroscopy and GLC. Yields after distillation were  $\sim 10\%$  lower. <sup>b</sup> Calculated in reference to the stoichiometric proportions  $Me_4Si/GeCl_4 = 4/1$  (mol). In this case  $MeSiCl_3$  also was formed in 30% yield.

As specified below, the formation of Me<sub>4</sub>Ge at the beginning of the reaction is observed regardless of the conditions used. It is for this reason that tetra-, tri-, di-, and finally monomethylations of GeCl<sub>4</sub> are successively described.

Tetramethylation of GeCl<sub>4</sub>. Tetramethylation of  $GeCl_4$  was performed according to eq 4.

$$\operatorname{GeCl}_{4} + 4\operatorname{Me}_{4}\operatorname{Si} \xrightarrow[200 \circ C]{\operatorname{AlBr}_{3}} \operatorname{Me}_{4}\operatorname{Ge} + 4\operatorname{Me}_{3}\operatorname{SiCl} \quad (4)$$

With 4.5 molar equiv of Me<sub>4</sub>Si and 3-5 mol % of AlBr<sub>3</sub> relative to  $GeCl_4$  (run 4, Table I), the conversion rate of GeCl<sub>4</sub> was 80% and Me<sub>4</sub>Ge was formed in 91% yield, together with Me<sub>3</sub>GeCl (9%) after 22 h at 200 °C. Me<sub>2</sub>SiCl<sub>2</sub> was not detected in any appreciable proportion, this likely being due to the equilibrium favoring Me<sub>3</sub>SiCl (eq 5).<sup>12,13</sup>

$$Me_4Si + Me_2SiCl_2 \rightleftharpoons 2Me_3SiCl$$
 (5)

Trimethylation of GeCl<sub>4</sub>. With 2 molar equiv of Me<sub>4</sub>Si relative to GeCl<sub>4</sub>, Me<sub>3</sub>GeCl was quantitatively formed (cf. run 10) (eq 6).

$$GeCl_4 + 2Me_4Si \xrightarrow[15 h, 200 \circ C]{} \xrightarrow{AlBr_3 (3-5 \mod \%)} \\ Me_3GeCl + Me_3SiCl + Me_2SiCl_2 (6) \\ 100\% 50\% 50\%$$

It is worth noting that two methyl groups can be exchanged in Me<sub>4</sub>Si; thus Me<sub>3</sub>SiCl also acts as a methylating reagent. This result was corroborated by experiments in which the reaction conditions were varied. Thus with 3 molar equiv of Me<sub>4</sub>Si relative to GeCl<sub>4</sub>, Me<sub>2</sub>SiCl<sub>2</sub> was formed as well as Me<sub>3</sub>SiCl (20%), but Me<sub>4</sub>Ge and Me<sub>3</sub>GeCl  $(\sim 20\%)$  were still present when equilibrium was achieved (over 15 h) (run 5).

**Dimethylation of GeCl**<sub>4</sub>. Optimum conditions required the use of  $Me_4Si/GeCl_4$  (ca. 1/1 molar equiv) (cf. run 13) as expected from the stoichiometry in eq 7.

$$\operatorname{GeCl}_{4} + \operatorname{Me}_{4}\operatorname{Si} \xrightarrow{\operatorname{AlBr}_{3}} \operatorname{Me}_{2}\operatorname{GeCl}_{2} + \operatorname{Me}_{2}\operatorname{SiCl}_{2} \quad (7)$$

#### Scheme I Me4Ge Me<sub>3</sub>GeCl (-MegGeCI) (I) MeGeCl<sub>3</sub> Me<sub>3</sub>GeCI (-Me\_SiCla) (II)GeCL (a) MezGeCI (b) Me<sub>3</sub>GeCl MeGeCl<sub>3</sub> (III) (-MegGeCla) le-GeCi-MeGeCl<sub>3</sub> (IV) (-MeGeCl.

Even after prolonged reaction times, Me<sub>3</sub>GeCl did not disappear completely (14% after 56 h). GeCl<sub>4</sub>, however, reacted completely and, as previously observed, Me<sub>3</sub>SiCl behaved as a methylating reagent and Me<sub>2</sub>GeCl<sub>2</sub> was formed in 86% yield.

Monomethylation of  $GeCl_4$ . An excess of  $GeCl_4$  is theoretically necessary to perform reaction 8.

$$2\text{GeCl}_4 + \text{Me}_4\text{Si} \xrightarrow[200 \circ \text{C}]{\text{AlBr}_3} 2\text{MeGeCl}_3 + \text{Me}_2\text{SiCl}_2 \quad (8)$$

In fact only 90% of the GeCl<sub>4</sub> was converted after 28 h, whereas Me<sub>4</sub>Si completely disappeared (cf. run 15). MeGeCl<sub>3</sub> and Me<sub>2</sub>GeCl<sub>2</sub> were formed in 64% and 36%yields, respectively, and  $Me_2SiCl_2$  was the only chlorosilane isolated (with  $Me_4Si/GeCl_4 = ca. 0.5/1$ ). Under these conditions, MeGeCl<sub>3</sub> seems to be more difficult to obtain because it easily undergoes subsequent methylation. Consequently, it was not possible to isolate MeGeCl<sub>3</sub> when the  $Me_4Si/GeCl_4$  ratio was greater than 2/1.

### Discussion

The behavior of intermediate and final products was examined as a function of the parameters of reaction time and the proportion of unreacted starting materials (Table I). This would suggest the following mechanism.

(a) Tetramethylation of GeCl<sub>4</sub>. This should be a fast reaction because Ge is large enough to undergo an easy tetramethylation despite the possible steric interactions among the four methyl groups (eq 9).

$$\operatorname{GeCl}_4 \xrightarrow{4\operatorname{Me}_4\operatorname{Si}} \operatorname{Me}_4\operatorname{Ge}$$
 (9)

(b) Redistribution Reactions between GeCl<sub>4</sub> and the Products Formed during the Course of Methylation.

Methylation was done by  $Me_4Si$  as previously observed during the synthesis of methylchlorogermanes from  $GeCl_4$ and  $Me_4Ge$  (Scheme I).<sup>10</sup>

These reactions could occur simultaneously.

With a very large excess of Me<sub>4</sub>Si (Me<sub>4</sub>Si/GeCl<sub>4</sub>  $\geq$  4/1), tetramethylation was almost the only reaction. Tetramethylation of GeCl<sub>4</sub> began relatively fast (53% conversion rate of GeCl<sub>4</sub> after 2.5 h (run 1, Table I)). MeGeCl<sub>3</sub> and Me<sub>2</sub>GeCl<sub>2</sub> seem to react faster than GeCl<sub>4</sub> as they were not detected in appreciable amounts (previously observed during butylation of GeCl<sub>4</sub><sup>8,11</sup>). Then the reaction slowed down; the conversion ratio of GeCl<sub>4</sub> reached 72, 73, and 80% after 8, 10, and 22 h, respectively, while the percentage of Me<sub>3</sub>GeCl present in the medium increased to 60% (after 8 h) and decreased between 8 and 22 h in favor of Me<sub>4</sub>Ge (runs 2-4, Table I).

Working with Me<sub>4</sub>Si/GeCl<sub>4</sub> < 4/1, the formation of Me<sub>3</sub>GeCl and Me<sub>4</sub>Ge was still observed at the beginning of the reaction regardless of the amount of Me<sub>4</sub>Si lacking. Thus, with Me<sub>4</sub>Si/GeCl<sub>4</sub> = 2/1 (reaction time betwen 2.75 and 4.5 h), only Me<sub>3</sub>GeCl (~20%) and Me<sub>4</sub>Ge (~80%) were formed (runs 6–8). Even with a large excess of GeCl<sub>4</sub> (Me<sub>4</sub>Si/GeCl<sub>4</sub> = 0.33/1), we initially observed the formation of Me<sub>3</sub>GeCl (74%) and Me<sub>4</sub>Ge (26%, run 16).

However, once the Me<sub>4</sub>Si had disappeared and the reaction time was prolonged, Me/Cl exchange between GeCl<sub>4</sub> or Me<sub>n</sub>GeCl<sub>4-n</sub> and Me<sub>4</sub>Ge, Me<sub>3</sub>SiCl, Me<sub>3</sub>GeCl, and perhaps Me<sub>2</sub>GeCl<sub>2</sub> was observed (reactions I–IV). Thus with Me<sub>4</sub>Si/GeCl<sub>4</sub> = 2/1 and a reaction time of 4.5–6 h, Me<sub>4</sub>Ge was observed to disappear, being progressively replaced by Me<sub>3</sub>GeCl and Me<sub>2</sub>GeCl<sub>2</sub> (reaction I), with Me<sub>3</sub>SiCl being accompanied by Me<sub>2</sub>SiCl<sub>2</sub> (runs 8 and 9, reaction II). After 6–15 h of reaction time, Me<sub>2</sub>GeCl<sub>2</sub> was completely converted to Me<sub>3</sub>GeCl (100%) by Me<sub>3</sub>SiCl (which gave the corresponding amount of Me<sub>2</sub>SiCl<sub>2</sub> (run 10, reaction IIc).

Methylation by Me<sub>3</sub>SiCl after 6 h was confirmed by runs 11 and 14. With Me<sub>4</sub>Si/GeCl<sub>4</sub> = 1/1, methylation from Me<sub>3</sub>SiCl was achieved after 22 h, the percentage of Me<sub>3</sub>GeCl decreasing because of its conversion into Me<sub>2</sub>GeCl<sub>2</sub> (disproportionation with MeGeCl<sub>3</sub>, reaction III, run 12). The yield of Me<sub>2</sub>GeCl<sub>2</sub> was optimized by continuing the reaction for 56 h (run 13) (the decrease of Me<sub>3</sub>GeCl and MeGeCl<sub>3</sub> was the same).

When  $Me_4Si/GeCl_4$  was decreased to 0.5/1,  $Me_4Si$ ,  $Me_4Ge$ ,  $Me_3SiCl$ , and  $Me_3GeCl$  were completely consumed by GeCl<sub>4</sub> after 28 h and formation of MeGeCl<sub>3</sub> was largely favored (64% of the methylchlorogermanes, run 15). A comparison of runs 14 and 15 showed the disproportionation of GeCl<sub>4</sub>/Me<sub>3</sub>GeCl as not being the only source of  $MeGeCl_3$  as it also results from the redistribution between  $GeCl_4$  and  $Me_2GeCl_2$  according to reaction IV.

As the final point, we note that when a very large excess of GeCl<sub>4</sub> was used (Me<sub>4</sub>Si/GeCl<sub>4</sub> = 0.33/1), the yield of MeGeCl<sub>3</sub> (68% of the formed methylgermanes) did not increase notably even after a 65-h reaction time (run 17). Quasi-equilibrium was reached after 28 h (run 15). It was observed, however, that because MeSiCl<sub>3</sub> was formed (run 17), Me<sub>2</sub>SiCl<sub>2</sub> acts as a methylation reagent according to eq 10 and 11.

$$GeCl_4 + Me_2SiCl_2 \xrightarrow{AlBr_3} MeGeCl_3 + MeSiCl_3$$
 (10)

$$MeGeCl_3 + Me_2SiCl_2 \xrightarrow{AlBr_3} Me_2GeCl_2 + MeSiCl_3 \quad (11)$$

In conclusion, we note that the reaction between GeCl<sub>4</sub> and Me<sub>4</sub>Si appears to be a versatile source of Me<sub>4</sub>Ge, Me<sub>3</sub>GeCl, Me<sub>2</sub>GeCl<sub>2</sub>, and even MeGeCl<sub>3</sub>. The product obtained is a result of varying the respective ratios of starting reagents and the reaction time.

# **Experimental Section**

Regardless of the proportions of GeCl<sub>4</sub> and Me<sub>4</sub>Si, specified in Table I, we worked with 10.75 g of GeCl<sub>4</sub> (50 mmol). Similarly 3-5 mol % of AlBr<sub>3</sub> (0.4-0.67 g) or AlCl<sub>3</sub> (0.2-0.33 g) with respect to GeCl<sub>4</sub> were introduced. Results summarized in Table I were obtained with 5 mol % of AlBr<sub>3</sub>; when 3 mol % was used, the reaction time was increased slightly to obtain the same yields.

Reagents were introduced with a syringe and weighed in an Erlenmeyer flask equipped with a sleeve stopper and previously cooled in an ice-water bath. In order to solubilize it and limit loss due to its volatility, Me<sub>4</sub>Si always was introduced after GeCl<sub>4</sub> when the reagents were poured into an autoclave (125 mL) containing previously cooled dry argon. The autoclave was agitated at the temperature and time specified in Table I. After being cooled in an ice-water bath, the reaction mixture was analyzed by NMR, mass spectrometry, and gas chromatography (columns, Versilube F 50, 25% on Chromosorb P DMSCS, or QF<sub>1</sub> (2-m length,  $^{1}/_{8}$ -in. diameter); Me<sub>2</sub>GeCl<sub>2</sub> and MeGeCl<sub>3</sub> not separable on Versilube thus were separated on QF<sub>1</sub> were separated on Versilube columns at 100 °C).

In order to avoid any modification of the reaction mixture during distillation, products were isolated upon distillation at temperatures lower than 100 °C after complexation of the Lewis acid with an excess of anhydrous NaCl. All products were identified by comparison of their NMR, mass spectra, or chromatography data with those of authentic samples.
