

$\alpha$ -acylation of 1-nitroalkanes<sup>1,2</sup>, the most widely employed method is based on the oxidation of 2-nitroalkanol **3**, readily available by the nitro-aldol (or Henry) reaction<sup>3</sup>. Recently, we have reported that pyridinium chlorochromate can be used to oxidize complex or polyfunctional 2-nitroalkanol **3** without affecting several functional or protecting groups<sup>4</sup>. The only shortcoming of this procedure are the long reaction times (30–36 h). In this communication we report on an improvement obtained by applying the phase transfer technique<sup>5</sup> to this kind of oxidation.

The reactions are carried out by slow addition at  $-10$  to  $-5^\circ\text{C}$  of potassium dichromate or potassium chromate and 30% sulfuric acid to a solution of 2-nitroalkanol **3** and tetra-*n*-butylammonium hydrogen sulfate (0.1 mol per mol **3**) in dichloromethane. The reaction proceeds smoothly to completion within 2 h. Under the phase transfer conditions, acid-labile protecting groups are retained and good yields of products **4** are obtained (Table).

Furthermore, a one-pot synthesis consisting of a solvent-free nitro-aldol reaction ( $1 + 2 \rightarrow 3$ ) on alumina followed by *in situ* oxidation to **4** under phase transfer conditions has been developed. We expect that this procedure will give ready access to this class of compounds.

#### $\alpha$ -Nitro Ketones **4** by Phase Transfer Oxidation of 2-Nitroalkanol **3**; General Procedure:

To a mechanically stirred solution of 2-nitroalkanol **3** (0.05 mol) and tetra-*n*-butylammonium hydrogen sulfate (1.7 g, 0.005 mol) in dichloromethane (90 ml) is added, slowly and simultaneously at  $-10^\circ\text{C}$ , 30% sulfuric acid (60 ml) and potassium dichromate or potassium chromate (0.065 mol). After further stirring for 2 h at  $-10^\circ\text{C}$ , 10% aqueous iron(II) sulfate (50 ml) is added and the layers are separated. The organic phase is dried with sodium sulfate and passed through a bed of Florisil (30 g). The solvent is removed under reduced pressure to afford the  $\alpha$ -nitro ketones **4** (Table).

#### One-Pot Synthesis of $\alpha$ -Nitro-Ketones (**4g–i**); General Procedure:

A mixture of the aldehyde **1** (0.05 mol) and the nitroalkane **2** (0.05 mol) is mechanically stirred for 2–3 min and then cooled in an ice-bath. After the addition of chromatographic alumina (Carlo Erta RS, activity I according to Brockmann;) and stirring at  $20^\circ\text{C}$  for 3 h, the mixture is allowed to stand for 20 h. Dichloromethane (90 ml) and tetra-*n*-butylammonium hydrogen sulfate (1.7 g, 0.005 mol) are added. Under stirring and cooling to  $-10^\circ\text{C}$ , 30% sulfuric acid (60 ml) and potassium dichromate (19.1 g, 0.065 mol) are simultaneously added, keeping the inner temperature at  $-10^\circ$  to  $-5^\circ\text{C}$ . After stirring for 2 h at  $-10^\circ\text{C}$ , the mixture is worked-up as above. The following yields are obtained; **4g**: 80%, **4h**: 72%, **4i**: 72%.

### Oxidation of 2-Nitroalkanol under Phase Transfer Conditions: A Mild and Efficient Synthesis of Linear $\alpha$ -Nitro Ketones

Goffredo ROSINI\*, Roberto BALLINI, Pietro SORRENTI, Marino PETRINI
