to obtain selectively alcohol **10a** with an (*R*) configuration at the resulting new chiral center. The best results were obtained with trialkylborohydride, i.e., potassium tri-*sec*-butylborohydride (K-Selectride) or lithium triethylborohydride (Super-H) which gave a 4:1 mixture of alcohols **10a** and **10b**, in quantitative yield. Fortunately, the two epimers were easily separated by column chromatography. Their stereochemistries were established based on the X-ray analysis of the minor isomer **10b**, which was isolated as a crystalline solid. Noteworthy was the obtention of a reverse diastereoselectivity¹⁰ upon treatment of ketone **4** with DIBAL-H.

Installation of the required 4-oxopent-1-yl moiety (see **2**) was envisioned by chain elongation of the hydroxymethyl group resulting from the opening of the oxazolidinone moiety of **10a**, following the benzylation of the free hydroxy group (Scheme 4). The required benzyl ether **11** was prepared in 86% yield from alcohol **10a** and then refluxed in a methanolic aqueous NaOH solution to deliver the corresponding amino alcohol **12** in 91% yield. At that point, we decided to introduce the 4-oxopent-1-yl appendage via a nucleophilic substitution of the corresponding tosylate by an appropriate organocuprate reagent. Bis-sulfonylation of amino alcohol **12** in the presence of tosyl chloride and Et₃N afforded in 60% yield derivative **13**, where the nitrogen atom has been protected¹¹ and the alcohol has been activated for nucleophilic substitution. Compound **13** was subsequently treated with a large excess of the cuprate species generated from the Grignard reagent of 4-bromo-2-butanone neopentyl glycol ketal and cuprous bromide.¹² Unfortunately, only the starting material was recovered along

Scheme 4

with the corresponding bromide. We then envisioned the formation of the desired carbon-carbon bond through a Wittig reaction. To this end, we first protected the amino function of compound **12** as a benzyl carbamate in 94% yield. Alcohol **14** was then oxidized under Swern conditions, and the resulting crude aldehyde thus obtained was subsequently involved in a Wittig reaction with the ylide, generated in situ from triphenylphosphonium bromide **15**.¹³ The resulting olefin **16**¹⁴ was isolated in 85% overall yield starting from alcohol **14**. Hydrogenation of the carbon-carbon double bond and reductive cleavage of both benzyloxy groups of compound **16** proceeded under an atmospheric pressure of hydrogen in the presence of Pd/C. The resulting ketal was then reacted under acid conditions to afford, via a tandem ketal cleavage/cyclization, the expected (-)-porantheridine (**1**), as the free base in 47% overall yield, after neutralization with Na₂CO₃. An analytical sample of this material displayed ¹³C and ¹H NMR spectra identical to those of synthetic racemic porantheridine.³ The optical rotation was determined to be [α]_D¹⁹ = -25° (c 0.50, CHCl₃), in good agreement with those obtained previously for natural¹ and synthetic² (-)-porantheridine, namely [α]_D = -26° (c 0.57, CHCl₃) and [α]_D²³ = -26.1° (c 0.38, CHCl₃), respectively.

In summary, the total synthesis of the naturally occurring alkaloid (-)-porantheridine has been achieved in nine steps and 20% overall yield from bicyclic amino ether **5**, readily available from L-lysine. This synthesis nicely documents the scope of our recently reported strategy for the stereocontrolled elaboration of trans 2,6-disubstituted piperidine substructures.

(9) As broadly estimated by ¹³C NMR, the use of NaBH₄, H₂/Raney-Ni, and bis(2-methoxyethoxy)aluminum hydride (Red-Al) gave respectively a 1:1, 2:3, and 1:3 epimeric mixture of **10a** and **10b**. Reactions with H₂/Pd-C and LiAlH(*t*-BuO)₃ were ineffective.

(10) Similar behavior was observed by G. Solladié and co-workers for the reduction of β-ketosulfonides: (a) Solladié, G.; Greck, C.; Demailly, G.; Solladié-Cavallo, A. *Tetrahedron Lett.* **1982**, 23, 5047-5050. Unlike these authors, the use of additives such as ZnCl₂, CeCl₃, and MgBr₂ did not affect the observed ratios in the case of the reduction of ketone **4**; (b) Solladié, G.; Demailly, G.; Greck, C. *Tetrahedron Lett.* **1985**, 26, 435-438.

(11) Protection of the nitrogen atom as carbamate was not conceivable here, since we previously noticed that tosylation of compound **6** quantitatively led to the obtention of the bicyclic oxazolidinone **3** through intramolecular nucleophilic displacement of the tosylate group by the carbamate moiety.

(14) According to ¹³C NMR, this Wittig reaction seemed to afford **16** as a single stereoisomer whose stereochemistry (*E* or *Z*) could not be assigned.

(2S,6S)-6-Allyl-N-(carbobenzyloxy)-2-(hydroxymethyl)-piperidine (6). A mixture of allyl oxazinone **3**⁴ (1.62 g, 8.95 mmol) and KOH (17.5 g, 312 mmol) in water (45 mL) and methanol (75 mL) was heated at 120 °C (bath temperature) for 63 h. After cooling to room temperature, brine (38 mL) and CH₂Cl₂ (125 mL) were added. The reaction mixture was stirred and then decanted, and the two phases were separated. The aqueous layer was extracted with CH₂Cl₂, and the combined organic layers were dried over Na₂SO₄ and concentrated in vacuo. The obtained crude amino alcohol was dissolved in CH₂Cl₂ (55 mL), and Na₂CO₃ (2.1 g, 19.8 mmol) was added. After cooling to 0 °C, benzyl chloroformate (1.40 mL, 9.81 mmol) was added dropwise. The reaction mixture was stirred for 16 h and then filtered and concentrated in vacuo. Column chromatography of the residue (3:7 EtOAc/cyclohexane) yielded alcohol **6** (1.45 g, 56%) as a yellow oil: $[\alpha]^{23}_D = -32^\circ$ (c 0.99, MeOH); ¹H NMR δ 7.40–7.15 (m, 5H), 5.75–5.50 (m, 1H), 5.15–4.85 (m, 4H), 4.30–4.12 (m, 1H), 3.95 (br s, 1H), 3.85–3.60 (m, 2H), 3.60–3.40 (m, 1H), 2.50–2.35 (m, 1H), 2.25–2.05 (m, 1H), 1.80–1.40 (m, 6H); ¹³C NMR δ 156.2, 136.5, 134.9, 128.5, 128.0, 127.8, 117.1, 67.0, 65.0, 55.1, 52.6, 36.2, 25.7 (2C), 16.9; IR (neat) 3450, 1690 cm⁻¹. (5S,8S)-8-(Hydroxymethyl)-3-(iodomethyl)hexahydropyridol[1,2-c][1,3]oxazin-1-one (7). To a solution of piperidine **6** (146 mg, 0.51 mmol) in CH₂Cl₂ (5 mL) at 0 °C was added iodine (519 mg, 2.05 mmol). The reaction mixture was stirred for 18 h at this temperature. After stirring at room temperature for 4 h more, a saturated aqueous solution of sodium thiosulfate (3 mL) was added. The organic layer was dried over Na₂SO₄ and concentrated in vacuo. Two successive column chromatography fractionations (3:7 EtOAc/cyclohexane then 1:9 EtOAc/cyclohexane) allowed the separation of the two diastereomers **7a** (35 mg, 21%) and **7b** (36 mg, 22%) as colorless liquids. (2S,6S)-N-(Benzyloxycarbonyl)-2-[3-(2,5,5-trimethyl[1,3]-dioxan-2-yl)propen-1-yl]-6-[(2R)-2-(benzyloxy)pentyl]piperidine (16). To a cooled solution of oxalyl chloride (190 μ L, 2.18 mmol) in CH₂Cl₂ (25 mL) at -78 °C was added dropwise DMSO (310 μ L, 4.37 mmol). After stirring for 15 min, a solution of alcohol **14** (616 mg, 1.45 mmol) in CH₂Cl₂ (5 mL) was added dropwise. The reaction mixture was stirred for 1 h at -78 °C, and then triethylamine (930 μ L, 6.68 mmol) was added. The reaction mixture was allowed to warm to room temperature.

Et₂O (50 mL) was then added, and the organic layer was washed with water before drying over Na₂SO₄. Concentration in vacuo afforded crude intermediate aldehyde.

To a cooled solution of triphenylphosphonium bromide **15**¹³ (1.81 g, 3.63 mmol) in THF (25 mL) at -40 °C was added a 1.35 M solution of *n*-BuLi in hexane (2.95 mL, 3.98 mmol). The mixture was stirred for 30 min at this temperature before the dropwise addition of a solution of the previously obtained aldehyde in THF (5 mL). The reaction mixture was allowed to warm to room temperature and stirred for 2 h more. Water (30 mL) and NaCl (1 g, 17 mmol) were then added. The aqueous layer was extracted with Et₂O. The combined organic layers were dried over Na₂SO₄ and concentrated in vacuo. Column chromatography (1:4 EtOAc/cyclohexane) yielded compound **16** (692 mg, 85%) as an orange oil: $[\alpha]^{19}_D = +37.9^\circ$ (c 1.05, MeOH); ¹H NMR δ 7.80–7.30 (m, 10H), 6.00–5.65 (m, 2H), 5.50–5.20 (m, 2H), 5.05–4.85 (m, 1H), 4.69 (AB q, $J = 11.5$ Hz, 2H), 4.45–4.25 (m, 1H), 3.80–3.50 (m, 5H), 2.85–2.65 (m, 2H), 2.40–1.35 (series of m including s at δ 1.55, 3H, total 15H), 1.30–0.85 (m, 9H); ¹³C NMR δ 155.9, 139.1, 137.0, 133.0, 128.5, 128.4, 127.8, 127.7, 127.4, 125.2, 98.9, 76.4, 70.4, 70.2, 66.8, 50.1, 49.8, 38.2, 36.0, 35.0, 30.0, 28.0, 25.6, 22.7, 22.6, 21.2, 18.6, 16.0, 14.3; IR (neat) 3050, 1705 cm⁻¹. Anal. Calcd for C₃₅H₄₉NO₅: C, 74.57; H, 8.76; N, 2.48. Found: C, 74.58; H, 8.86; N, 2.42.

Porantheridine (1). Compound **16** (198 mg, 0.35 mmol) dissolved in MeOH (10 mL) was subjected to hydrogenation (1 atm) in the presence of 10% Pd/C (198 mg) at room temperature for 5 h. The mixture was then filtered over a Celite pad, which was rinsed with MeOH. The solvent was evaporated in vacuo yielding an intermediate amino alcohol (110 mg, 92%). A mixture of the latter and *p*-TsOH (65 mg, 0.34 mmol) in benzene (5 mL) was stirred at reflux temperature for 3 h, at which point 4 Å molecular sieves (3 g) were added. Stirring at reflux temperature was continued for 3 h. The reaction mixture was then filtered and the solid residue washed with Et₂O. The organic layer was stirred in the presence of Na₂CO₃ (2 g, 19 mmol) for 15 min before filtration and evaporation of the solvent in vacuo. Column chromatography (2:8 CH₂Cl₂/MeOH) of the residue yielded expected porantheridine (**1**) (39 mg, 47% from **16**) as a colorless oil: $[\alpha]^{19}_D = -25^\circ$ (c 0.50, CHCl₃); ¹H NMR δ 4.05–3.85 (m, 1H), 3.80–3.60 (m, 1H), 3.05–2.85 (m, 1H), 2.05–1.10 (series of m, 21H), 0.92 (t, $J = 7$ Hz, 3H); ¹³C NMR δ 86.2, 69.1, 49.5, 48.4, 40.0, 39.2, 34.1, 34.0, 30.8, 27.3, 23.7, 19.7, 19.3, 18.0, 14.3.
