The reaction of PtCl₂(NCPH)₂ with the ylide [Ph₃P=C(H)COCH₂PPh₃]₂ClO₄ (1 : 1 molar ratio, refluxing CHCl₃) affords *trans*-[PtCl₂(NCPH){C(H)PPh₃C(O)CH₂PPh₃}]₂ClO₄ **1**. However, the reaction of PtCl₂(CH₂Cl₂, r.t.) or PtCl₂(NCMe)₂ (2-methoxyethanol, reflux) with the ylide [Ph₃P=C(H)COCH₂PPh₃]₂ClO₄ (1 : 1 molar ratio) affords the orthometallated [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(μ-Cl)]₂(ClO₄)₂, **2**, as a mixture of diastereoisomers **2a–d**. Treatment of **2** with PPh₃ (1 : 2 molar ratio) affords [PtCl{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(PPh₃)](ClO₄), **3**, as a single geometric isomer. The reaction of **2** with AgClO₄ (1 : 2 molar ratio) in NCMe gives the solvato complex [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(NCMe)₂](ClO₄)₂, **4**, while the reaction of **2** with Tl(acac) (1 : 2 molar ratio) gives [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(acac)](ClO₄), **5**. The dicationic complexes [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(dppe)](ClO₄)₂, **6**, and [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(phen)](ClO₄)₂, **7**, can be obtained by reaction of **2** with AgClO₄ followed by addition of the appropriate ligand (1 : 2 : 2 molar ratio). The reaction of **6** with NaH gives [Pt{C₆H₄-2-PPh₂C(H)COCH=PPh₃}(dppe)](ClO₄), **8**, while the reaction of **4** with PPh₃ and NaH gives [Pt{C₆H₄-2-PPh₂C(H)COCH=PPh₃}(PPh₃)₂](ClO₄), **9**. Complexes **8** and **9**, which contain a “free ylide” functionality, react with ClAu(tht) to give [Pt{C₆H₄-2-PPh₂C(H)COCH(AuCl)PPh₃}(dppe)](ClO₄), **10**, and [Pt{C₆H₄-2-PPh₂C(H)COCH(AuCl)PPh₃}(PPh₃)₂](ClO₄), **11**. In the heterobimetallic complexes **10** and **11** the ylide ligand acts as a C,C,C-terdentate ligand and, in spite of the presence of two chiral centers, only one diastereoisomer (as the mixture of two enantiomers) is observed. All complexes were characterized on the basis of their spectroscopical and analytical parameters.

One of our main current research subjects is the coordination chemistry of Pd^{II} and Pt^{II} with α-stabilized phosphoylides.¹ Amongst them, the neutral bis-ylide [C(H)=PPh₃]₂CO has shown a notable reactivity, not only in Pd^{II} derivatives^{2–5} but also in gold and silver complexes, as it has been reported by other research groups.⁶ One of the most interesting reactions of this bis-ylide is its intramolecular rearrangement from the C,C-chelating form [C(H)PPh₃]₂CO to the C,C-orthometallated form [C₆H₄-2-PPh₂C(H)COCH₂PPh₃],³ which can be induced through a variety of methods. This rearrangement occurs through a C–H bond activation process in one Ph group of a PPh₃ fragment, followed by an acid-base intramolecular reaction.³ Pt^{II} complexes have been employed frequently to promote C–H bond activation,⁷ and interest in cycloplatination reactions is growing continuously (as evidenced by the number of contributions that have appeared in this field^{8–20}), because of their practical importance.²¹ On the other hand, although the orthometallation of ylide ligands is a known reaction, not only for the platinum group metals^{22–29} but also in early transition metals such as Nb,³⁰ the subsequent reactivity of the orthometallated ylide ligands has been rarely reported.^{4,5,24}

Due to our interest in C–H bond activation processes and in orthometallated systems derived from ylide groups, we have decided to explore the reactivity of some simple complexes of Pt^{II} such as PtCl₂ or PtCl₂(NCR)₂ (R = Me, Ph) towards the phosphonium ylide salt [Ph₃P=C(H)C(O)CH₂PPh₃]₂ClO₄. In the case of the nitrile complexes one should expect, at a first glance, a simple displacement of the coordinated nitrile by the incoming ylide, but it has been previously reported that the reactions of PtCl₂(NCR)₂ (R = Me, Ph, C₆F₅) with stabilized

ylides are actually more complicated, giving different types of C–C bond coupling products,^{31–33} resulting from the nucleophilic attack of the C_α of the ylide on the nitrilic carbon. Thus, several reactivity patterns should be considered in this kind of reaction.

In this paper, we report different synthetic methods to achieve the orthometallation of the phosphonium ylide [Ph₃P=C(H)C(O)CH₂PPh₃]₂ClO₄ promoted by Pt^{II} complexes. Interestingly, the reactions of the nitrile precursors PtCl₂(NCPH)₂ and PtCl₂(NCMe)₂ with the aforementioned phosphonium ylide proceed without attack over the coordinated nitriles and, in some cases, afford the orthometallated derivatives under very mild conditions (CH₂Cl₂, r.t.). We have also studied the reactivity of the C,C-orthometallated derivatives [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}L_n]ⁿ⁺ towards deprotonating reagents, which results in the synthesis of “free-ylide”-containing complexes [Pt{C₆H₄-2-PPh₂C(H)COCH=PPh₃}L_n]⁽ⁿ⁻¹⁾⁺ and their subsequent reactivity towards electrophilic reagents, such as ClAu(tht) (tht = tetrahydrothiophene), to afford the heterobimetallic species [Pt{C₆H₄-2-PPh₂C(H)COCH(AuCl)PPh₃}L_n]⁽ⁿ⁻¹⁾⁺, in which the orthometallated ylide group acts as a C,C,C-terdentate ligand.

Results and discussion

Reactivity of PtCl₂(NCR)₂ and PtCl₂ with [Ph₃P=C(H)C(O)CH₂PPh₃]₂ClO₄

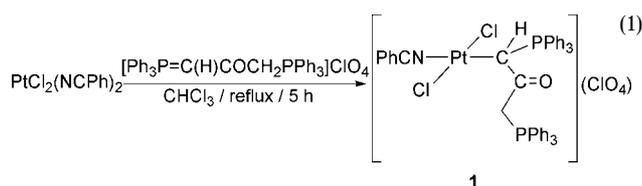

The reaction of PtCl₂(NCPH)₂ with [Ph₃P=C(H)C(O)CH₂PPh₃]₂ClO₄ (1 : 1 molar ratio, CHCl₃, reflux, 5 h) results in the formation of *trans*-[PtCl₂(NCPH)-{C(H)PPh₃-

C(O)-CH₂PPh₃}]ClO₄, **1**, eqn. (1), according to its analytical and spectroscopic data (see Experimental). The reaction occurs by simple displacement of only one coordinated nitrile and its substitution by the ylide, which coordinates through the ylidic C atom. This result contrasts with related reports of the reactivity of Pt^{II}-nitrile complexes with α -keto-stabilized ylides R₃P=C(H)CO₂R, which result in the attack of C_α on the coordinated nitrile.^{31–33} The difference in the observed reactivity could be related to the different basicity associated with the ylidic carbon.

The stretching ν (CO) band appears at 1654 cm⁻¹ in the IR spectrum, clearly shifted to higher frequencies with respect to the starting ylide (1590 cm⁻¹)⁶ and suggesting its C-coordination. The Cl-*trans*-to-Cl geometry of **1** can be inferred from the observation of only one Pt–Cl absorption (309 cm⁻¹), and the presence of coordinated NCPH from the absorption located at 2300 cm⁻¹. The ¹H NMR spectrum shows the resonance attributed to the ylidic CH proton at 6.22 ppm, as a broad singlet, and flanked by ¹⁹⁵Pt satellites. The value of the coupling constant ²J_{Pt-H} = 117 Hz is in good agreement with previously reported values for Pt^{II} C-bonded ylides.^{26,34} This spectrum shows also the presence of the AB part of an ABX spin system, attributed to the methylene protons of the –CH₂PPh₃ group (see Experimental). In addition, the ³¹P{¹H} NMR spectrum shows the two chemically inequivalent P atoms as two doublets (⁴J_{P-P} = 10 Hz), one of them showing ¹⁹⁵Pt satellites (²J_{Pt-P} = 76 Hz), and the ¹³C{¹H} NMR spectrum confirms the C-bonding of the ylide [Ph₃PC(H)C(O)CH₂PPh₃]ClO₄ since the ylidic carbon appears at 21.52 ppm as a doublet of doublets, although due to the low intensity of the resonance we were unable to find the corresponding platinum satellites. The presence of coordinated NCPH was also evident from the ¹³C{¹H} NMR spectrum since the nitrilic carbon appears at 114.99 ppm, typical for coordinated nitriles.³⁵

Complex **1** has the ylide [Ph₃PC(H)C(O)CH₂PPh₃]ClO₄ selectively coordinated through the ylidic carbon. This result contrasts with those obtained in Pd^{II} complexes, in which we were unable to obtain this coordination mode.² As far as we know, only one example of this bonding mode has been reported, the gold(I) derivative [AuCl{CH(PPh₃)COCH₂PPh₃}]ClO₄.⁶ Owing to the presence of the phosphonium moiety in **1**, and due to our recent experience in the deprotonation of related systems,^{4,5} we have performed several reactions in order to obtain Pt^{II} derivatives with the C,C-chelating ligand [C(H)PPh₃]₂CO, which should arise from direct deprotonation of **1** and simultaneous abstraction of one chloride ligand. However, the reactivity of **1** towards deprotonating reagents such as NaH (1 : 1 molar ratio, THF, r.t.), NBu₄OH (1 : 1 molar ratio, MeOH, r.t.), Tlacc (1 : 1 or 1 : 2 molar ratio, CHCl₃, r.t. or reflux) or (acac)AuPPh₃ (1 : 1 molar ratio, CH₂Cl₂, r.t.) only gave intractable mixtures of several products, which were not analyzed further.

Other reactions were performed in order to obtain complexes related to **1** with the ylide C-bonded. However, PtCl₂(NCMe)₂ does not react with [Ph₃P=C(H)C(O)CH₂PPh₃]ClO₄ under the same conditions (1 : 1 molar ratio, CHCl₃, reflux, 5 h) and the starting materials were recovered. Probably, the different lability of the two nitrile ligands accounts for this different reactivity. Moreover, PtCl₂ reacts with [Ph₃P=C(H)C(O)CH₂PPh₃]ClO₄ (1 : 1 molar ratio, CH₂Cl₂, r.t., 4 days) but gives a very different complex. At the end of the reaction time, the PtCl₂ is almost completely

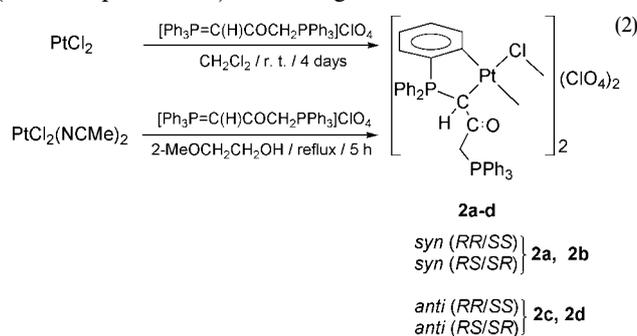

dissolved. After filtration, removal of the solvent and Et₂O addition, the mixture of the orthometallated complexes **2a–d** is obtained as a cream solid [see eqn. (2) (top)]. The presence of four isomers can be inferred from the NMR spectra (see below and Experimental) but two of the isomers, **2a** and **2b**, are always present in higher amounts than the other two, **2c** and **2d**.

The mild conditions employed in the cycloplatination of the phosphonium ylide [Ph₃P=C(H)C(O)CH₂PPh₃]ClO₄ contrast with the previous reports of orthometallation of stabilized ylides. Thus, the ylide Ph₃P=C(H)COMe is orthometallated by reaction with PtCl₂ in refluxing NCMe for 44 h,²² while the complex *trans*-PtCl₂{C(H)PPh₃C(O)Me}₂ evolves in refluxing THF (8 h) or refluxing NCMe (44 h), resulting in the formation of {PtCl₂[CH(COCH₃)PPh₂(*o*-C₆H₄)]-[Ph₃PCH₂COCH₃]}₂.²⁶ However, the authors also reported that the latter transformation can also be performed in CH₂Cl₂ at room temperature for several days.²⁶

In order to shed light on the kinetic or thermodynamic nature of the different pairs of isomers **2a, b** and **2c, d** obtained and since the orthometallation of the ylides is usually promoted at high temperatures, we have refluxed equimolar amounts of PtCl₂(NCMe)₂ and [Ph₃P=C(H)C(O)CH₂PPh₃]ClO₄ in different solvents. The best results were obtained in 2-methoxyethanol, a solvent that has been employed in the orthometallation of bulky tertiary phosphines.³⁶ The reaction of PtCl₂ with [Ph₃P=C(H)C(O)CH₂PPh₃]ClO₄ in 2-methoxyethanol [1 : 1 molar ratio, reflux, 5 h, see eqn. (2) (bottom)] results in the almost exclusive formation of the isomers **2c, d** according to the NMR data. Thus, it seems that the isomers obtained at room temperature, **2a, b**, are the kinetic isomers and those obtained at higher temperatures, **2c, d**, are the thermodynamic isomers. Additional proof comes from the observation that a mixture of **2a, b** subjected to prolonged heating in 2-methoxyethanol evolves to a mixture of **2c, d**.

The mixture of complexes **2a–d** has elemental analysis and mass spectrum in accordance with the stoichiometry [Pt(Cl)(C₆H₄PPh₂C(H)COCH₂PPh₃)]₂(ClO₄)₂ (see Experimental). Moreover, its IR spectrum shows the carbonyl stretch at 1652 cm⁻¹ and the absorptions corresponding to the Pt–Cl stretch at 283 cm⁻¹, shifted to lower energies when compared with **1**, suggesting the presence of bridging halide ligands.

The characterization of complexes **2a–d** as a mixture of diastereoisomers containing the orthometallated [C₆H₄-2-PPh₂C(H)COCH₂PPh₃] ligand has been made on the basis of their NMR data. The ¹H NMR spectrum of **2a–d** shows the presence of four different resonances attributed to the ylidic Pt–CH protons and four AB parts of ABX spin systems, attributed to the methylene protons of the –CH₂PPh₃ groups (X = ³¹P nucleus). The ³¹P{¹H} NMR of **2a–d** shows also the presence of four sets of AX spin systems: the part A of the resonances appears centered around 20 ppm (–CH₂PPh₃) and the part X appears spread from 24 to 30 ppm (PPh₂). The ¹³C{¹H} NMR spectrum provides fundamental evidence for the presence of the orthometallated C,C-chelating ligand [C₆H₄-2-PPh₂C(H)COCH₂PPh₃]. Thus, the APT spectrum (attached proton test) shows negative doublet resonances in

the range 135–144 ppm, the typical region for the appearance of the orthometallated C₁ carbon atom {the reported value for [Pt(μ-Cl)CH₃COCHP(C₆H₄(C₆H₅)₂)₂ · 2 CDCl₃ is 136.9 ppm].²²

Once the orthometallated dinuclear nature of complexes **2** is established, the explanation of the presence of four different isomers could be explained by assuming that we have two different arrangements of the [Pt(Cl)(C₆H₄PPh₂-C(H)COCH₂PPh₃)] fragments: *syn* and *anti*. In turn, the *syn* isomer possess two chiral centers (the two ylidic carbon atoms bonded to the Pt center) and thus we have again two possibilities: *syn* (RR/SS) and *syn* (RS/SR), which appear as two different products. In the same way, we could have *anti* (RR/SS) and *anti* (RS/SR) thus giving four different diastereoisomers, each as the racemic mixture of two enantiomers. The assignment of the *anti* isomers to the products **2c**, **d** has been made by similarity of the chemical shifts, and of the shape of the resonances of the ¹H NMR spectrum of the mixture, with those observed in the corresponding Pd^{II} complex³ [Pd(μ-Cl){C₆H₄-2-PPh₂C(H)COCH₂PPh₃}]₂(ClO₄)₂, which proved to be the *anti* isomers.⁴ Thus, the compounds **2a**, **b** have been assigned to the *syn* isomers.

With respect to the mechanism of the orthometallation, we have some evidence to believe that the reaction in CH₂Cl₂ occurs in a similar way to that described²⁶ for the cycloplatination of [PtCl₂{C(H)PPh₃C(O)Me}]₂. In this report, the intramolecular metallation seems to be promoted by the presence of traces of HCl and it is completely inhibited in the presence of K₂CO₃. In the same way, we have performed the reaction of PtCl₂ with equimolar amounts of [Ph₃P₂C(H)C(O)CH₂PPh₃](ClO₄) in CH₂Cl₂ and in THF, in the presence or absence of Na₂CO₃, and we have observed cycloplatination only in the reaction carried out in CH₂Cl₂ in the absence of Na₂CO₃ (all reactions at room temperature). We have not performed experiments in order to ascertain which mechanism operates in the thermal orthometallation in 2-methoxyethanol.

Reactivity of the cycloplatinated derivatives **2a–d**

Obviously, the reactivity of the four isomers in cleavage reactions of the chloride bridging system is the same. The reaction of **2a–d** (different molar ratios **a** : **b** : **c** : **d**) with PPh₃ (1 : 2 molar ratio) gives [Pt(Cl){C₆H₄-2-PPh₂C(H)COCH₂-PPh₃}(PPh₃)](ClO₄), **3**, as a single isomer and in good yields (see Scheme 1). When the reaction is monitored by ³¹P{¹H} NMR (CD₂Cl₂, r.t.) the spectroscopic yield of **3** is 100%, and we have not detected unreacted **2** in the solution, nor other isomers of **3**. Complex **3** was obtained, in preparative scale, after evaporation of the solvent to dryness and addition of MeOH or Et₂O as a white solid. Its elemental analysis and mass spectrum are in good agreement with the proposed stoichiometry. The IR spectrum of **3** shows the carbonyl absorption at 1643 cm⁻¹ and the Pt–Cl stretch at 283 cm⁻¹, typical for a terminal chloride trans to a carbon atom.²⁶ Further characterization of **3** comes from the analysis of its NMR data. The ¹H NMR spectrum shows only one set of resonances, suggesting the presence of a single geometric isomer. The ylidic CH proton appears at 4.84 ppm as a doublet of doublets of doublets, due to its coupling with three different P atoms, and suggesting that the PPh₃ ligand is trans to the ylidic carbon, as it has been observed in its Pd homolog. The methylenic CH₂P protons appear at 4.95 and 5.73 ppm, as the AB part of an ABX spin system (X = ³¹P). The ³¹P{¹H} NMR spectrum of **3** shows the presence of only one set of three resonances, corresponding to the three chemically inequivalent P nuclei of the molecule. The coordinated PPh₃ appears at 24.10 ppm as a doublet with ¹⁹⁵Pt satellites (¹J_{Pt-P} = 3623 Hz), the P atom in the cycloplatinated ring appears at 21.90 ppm as a doublet of doublets with unresolved

¹⁹⁵Pt satellites (a broadening of the base of the signal) and the phosphonium group appears at 20.17 ppm as a doublet.

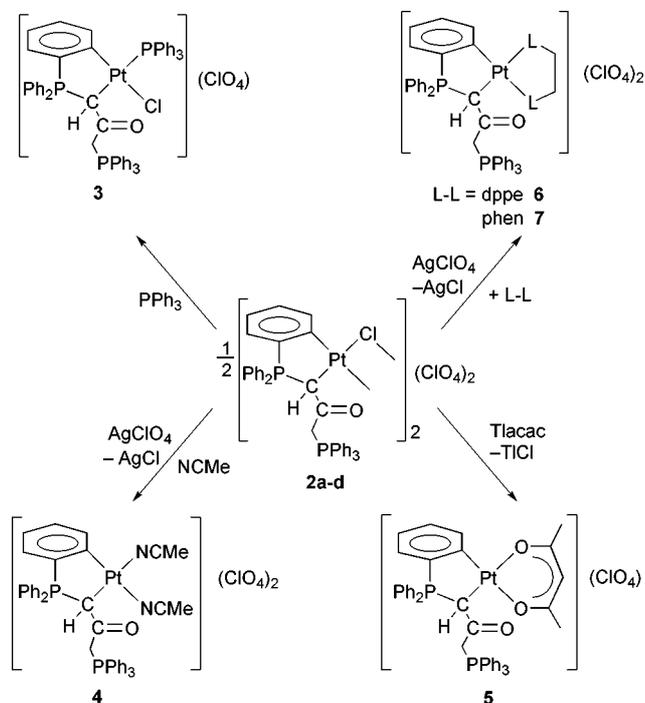

The synthesis of **3** as a single isomer resembles that of the related Pd(II) derivative [Pd(Cl){C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(PPh₃)](ClO₄).³ In the Pd(II) complex, this selectivity was explained taking into account the anti-symbiotic behavior of the soft Pd(II) metal center,^{1,37–41} and similar arguments can be invoked here to explain this similar selectivity of the soft Pt(II) center.^{37,39} In our experience, in all complexes of Pd^{II} and Pt^{II} containing the *neutral* orthometallated ligand [C₆H₄-2-PPh₂C(H)COCH₂PPh₃], the coordination of an incoming phosphine ligand always occurs at the trans position to the ylidic carbon. It has been recently reported that the mutual destabilizing effect of trans ligands increases with their trans influence.⁴¹ According to this effect, and taking into account that the trans influence of the aryl group is higher than that of the phosphine ligand (Ar > PR₃), the decreasing order of destabilizing effects should be Ar/Ar > Ar/PR₃ > PR₃/PR₃.⁴¹ This effect has been called *transphobia*.^{41,42}

We can now propose the inclusion of a new member in this sequence, according to our experimental data. Since it seems that the trans influence decreases in the order Ar > C_{ylide} > PR₃, the latter sequence of destabilizing effects could be extended as follows: Ar/Ar > Ar/C_{ylide} > Ar/PR₃ > C_{ylide}/PR₃ > PR₃/PR₃, though we do not yet have experimental evidence to include in a precise position the term C_{ylide}/C_{ylide}. The trends described here have found wide support in the experimental work.

Nevertheless, we are aware of the existence of exceptions to this rule, some of which have been reported by us⁴ and by other authors,²⁵ but, in general, the *transphobia* rule gives accurate predictions. It is clear that antisymbiosis and the trans influence are not the sole parameters governing the final stereochemistry of a given complex. For instance, subtle variations in the ligands can alter dramatically the predicted stereochemistry, as in the case of [Pd(Cl){C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(PPh₃)](ClO₄) (1 isomer)³ and [Pd(Cl){C₆H₄-2-PPh₂C(H)COCH=PPh₃}(PPh₃)] (2 isomers),⁴ for which the only difference is the presence of a phosphonium fragment or an ylide group, respectively, or in the case of the complex [PdCl{κ²-C₆H₃[PTO₂-CH(Py-2')-2]Me-4}(PEt₃)₂],²⁵ which is obtained as a mixture of two isomers (PEt₃ *trans* C_{aryl} and PEt₃ *trans* C_{ylide}).

On the other hand, the solvate [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(NCMe)₂](ClO₄)₂, **4**, can be obtained, as a white solid, by reaction of the mixture **2a–d** with AgClO₄ (1 : 2 molar ratio) in NCMe at room temperature, filtration of the precipitated AgCl, evaporation of the solvent to dryness and treatment of the oily residue with *n*-hexane. The elemental analysis and mass spectrum of **4** are in good agreement with the proposed stoichiometry. The presence of two NCMe ligands can be inferred from the IR spectrum (absorptions at 2322 cm⁻¹), which also shows the ν(CO) band at 1670 cm⁻¹. The ¹H NMR spectrum shows the presence of resonances attributed to two nitrile ligands (two singlets at 2.46 and 2.41 ppm), to the ylidic CH proton (a doublet at 5.33 ppm) and to the methylene protons. The last resonance appears as a doublet (instead of a well-resolved AB spin system), probably due to isochrony of the two protons, which transforms the AB spin system into an A₂ system.⁴³ This deceptively simple A₂ spin system is coupled with the ³¹P nucleus with the same coupling constant (²J_{P-H} = 12.3 Hz). The ³¹P{¹H} NMR spectrum shows, as expected, an AX spin system (30.03 and 21.06 ppm).

The chlorine ligands in **2** can be substituted by the acac ligand (acac = acetylacetonate) by reaction of **2** with Ti(acac) (1 : 2 molar ratio, CH₂Cl₂, r.t.). After removal of the TiCl and solvent evaporation, the complex [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(acac)](ClO₄), **5**, (see Scheme 1) was

Scheme 1

obtained, according to its elemental analysis and mass spectrum. The spectroscopic data of **5** are also in keeping with the proposed stoichiometry. The IR spectrum shows absorptions attributed to the carbonyl stretch of the ylide (1656 cm^{-1}) and to the acac ligand (1558 and 1520 cm^{-1}). The ^1H NMR shows the expected resonances for the CH (acac) proton (5.24 ppm), the CH_2P protons (5.25 ppm), the CH (ylide) proton (4.71 ppm) and the methyl (acac) protons (1.89 and 1.58 ppm). Once again, the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum shows an AX spin system (30.36 and 21.12 ppm).

Finally, dicationic complexes of stoichiometry $[\text{Pt}\{\text{C}_6\text{H}_4\text{-2-PPh}_2\text{C(H)COCH}_2\text{PPh}_3\}(\text{L-L})](\text{ClO}_4)_2$ ($\text{L-L} = \text{dppe}$ **6**, phen **7**) can be obtained by reaction of **2** with AgClO_4 (1 : 2 molar ratio, THF, r.t) (see Scheme 1), filtration of the AgCl , and subsequent addition of the L-L ligands (molar ratio 2 : $\text{L-L} = 1 : 2$) to the resulting solution of the solvated species $[\text{Pt}\{\text{C}_6\text{H}_4\text{-2-PPh}_2\text{C(H)COCH}_2\text{PPh}_3\}(\text{THF})_x](\text{ClO}_4)_2$. The analytical and spectroscopic data of **6** and **7** are in good agreement with the proposed stoichiometry. The IR spectra show absorptions attributed to the carbonyl stretch of the ylide, which in both cases appears at 1657 cm^{-1} . The ^1H NMR spectra show the expected resonances for the dppe or the phen groups in an asymmetric environment (inequivalence of the two halves of each ligand). In addition, the ^1H NMR spectrum of **6** shows the CH (ylide) as a triplet (5.36 ppm ,

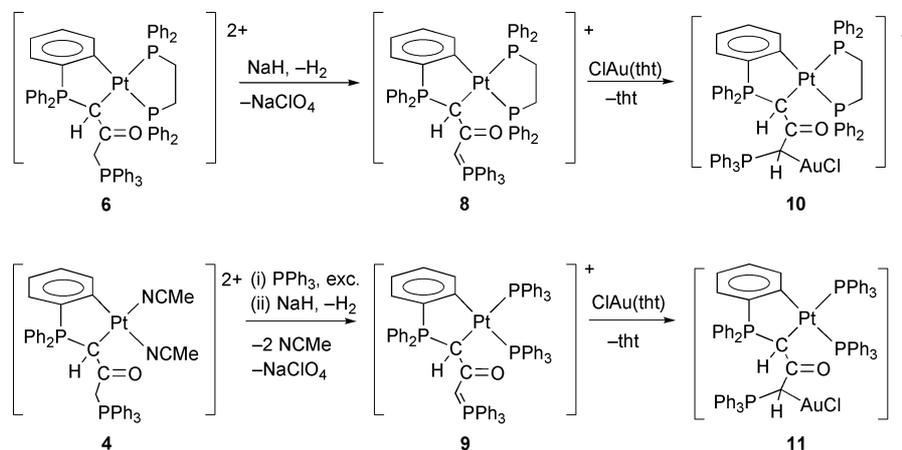

$^2J_{\text{P-H}} = ^3J_{\text{Ptrans-H}} = 6.3\text{ Hz}$) with ^{195}Pt satellites ($^2J_{\text{Pt-H}} = 80\text{ Hz}$) and the diastereotopic CH_2P protons (4.29 and 3.78 ppm) as the AB part of an ABX spin system. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **6** shows the presence of four resonances corresponding to the four chemically inequivalent P atoms of the molecule. For complex **7**, the CH (ylide) proton appears at 5.80 ppm and the CH_2P protons at 5.47 and 5.15 ppm . As expected, the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **7** shows an AX spin system (26.55 and 20.79 ppm).

Deprotonation of complexes 3–7

Owing to the presence of the phosphonium group $-\text{C}(\text{O})\text{CH}_2\text{PPh}_3$ in complexes **3–7**, we have attempted the deprotonation of these compounds with a variety of bases in order to obtain neutral or monocationic derivatives containing the free ylide unit $-\text{C}(\text{O})\text{C}(\text{H})=\text{PPh}_3$, in a similar way to that described for Pd complexes.⁴ However, the reactivity of **3–7** with bases such as NBu_4OH , which have given excellent results in Pd complexes,⁴ did not give clean reactions in this case and complex mixtures were obtained. The same results were observed in the reaction of **3** with NaH , and the reaction of **4** or **5** with NaH was not attempted.

The reactivity of **6** with NaH was more successful. Thus, the treatment of a THF suspension of **6** with an excess of NaH affords the monocationic derivative $[\text{Pt}\{\text{C}_6\text{H}_4\text{-2-PPh}_2\text{C(H)COCH}=\text{PPh}_3\}(\text{dppe})](\text{ClO}_4)$, **8**, (see Scheme 2) according to its elemental analysis and mass spectrum (see Experimental). The IR spectrum of **8** shows the carbonyl absorption at 1529 cm^{-1} , that is, shifted 128 cm^{-1} to lower energies with respect to the starting compound **6** and in good agreement with the presence of the free ylide unit $-\text{C}(\text{O})\text{C}(\text{H})=\text{PPh}_3$. The NMR spectra provide further characterization. The ^1H NMR spectrum shows, in addition to the aromatic resonances and those expected for the methylene protons of the dppe ligand, a triplet centered at 4.15 ppm (attributed to the Pt-CH proton) and a new doublet at 3.09 ppm (relative intensity 1 : 1). This last resonance showing a value of the coupling constant $^2J_{\text{P-H}}$ of 25.2 Hz , very similar to those observed for the free ylides, and which is attributed to the ylidic proton of the “free ylide” group. The $^{31}\text{P}\{^1\text{H}\}$ NMR is also in good agreement with the proposed stoichiometry, since the resonance at 21.13 ppm in the starting product **6** is not observed and a new resonance at 13.60 ppm appears, corresponding to the free ylide phosphorus.

The synthesis of complex $[\text{Pt}\{\text{C}_6\text{H}_4\text{-2-PPh}_2\text{C(H)COCH}=\text{PPh}_3\}(\text{PPh}_3)_2](\text{ClO}_4)$, **9**, (see Scheme 2) is not as straightforward as that described for complex **8**. The reaction of the bis-acetonitrile complex **4** with an excess of PPh_3 should result in the replacement of the two NCMe ligands by two PPh_3 groups or, at least, in the exchange of one NCMe by one PPh_3 , giving the complex $[\text{Pt}\{\text{C}_6\text{H}_4\text{-2-}$

Scheme 2

$\text{PPh}_2\text{C}(\text{H})\text{COCH}_2\text{PPh}_3\{(\text{PPh}_3)(\text{NCMe})\}(\text{ClO}_4)_2$, by analogy to the observed behavior in Pd(II) complexes.³ Thus, although the bis-phosphine derivative $[\text{Pd}\{C_6H_4-2-PPh_2C(\text{H})COCH_2PPh_3\}(\text{PPh}_3)_2](\text{ClO}_4)_2$ could not be obtained, the complex $[\text{Pd}\{C_6H_4-2-PPh_2C(\text{H})COCH_2PPh_3\}(\text{PPh}_3)(\text{NCMe})](\text{ClO}_4)_2$, containing one PPh_3 group, was synthesized in high yield and characterized crystallographically.³ However, by reaction of **4** with PPh_3 in different molar ratios, we have not been able to obtain a compound with a defined stoichiometry by simple exchange of ligands.

Nevertheless, we have attempted the deprotonation of **4** in the presence of PPh_3 . Thus, a suspension of **4** in THF was treated with an excess of PPh_3 , resulting in the gradual dissolution of the starting compound. This solution was then allowed to react with NaH, and the subsequent workup (see Experimental) gives the desired deprotonated compound $[\text{Pt}\{C_6H_4-2-PPh_2C(\text{H})COCH_2PPh_3\}(\text{PPh}_3)_2](\text{ClO}_4)$, **9**, although in moderate yield (58%). This behavior is somewhat related to that observed in the palladium complexes. Thus, although $[\text{Pd}\{C_6H_4-2-PPh_2C(\text{H})COCH_2PPh_3\}(\text{PPh}_3)_2](\text{ClO}_4)_2$ could not be³ synthesized, its deprotonated form $[\text{Pd}\{C_6H_4-2-PPh_2C(\text{H})COCH=PPh_3\}(\text{PPh}_3)_2](\text{ClO}_4)$ can be obtained and it is stable, both in the solid state and in solution.⁵

The elemental analysis and mass spectrum of **9** are in good agreement with the proposed stoichiometry. The IR spectrum shows the carbonyl stretch at 1531 cm^{-1} , in the same region as that observed for **8**. The ^1H NMR spectrum shows the presence of a very complex multiplet with ^{195}Pt satellites at 3.62 ppm, attributed to the ylidic Pt–C(H) proton and a doublet at 3.89 ppm, with a value of the coupling constant $^2J_{\text{P-H}}$ of 26.1 Hz. Both facts are in keeping with the presence of the free ylide group $-\text{C}(\text{O})-\text{C}(\text{H})=\text{PPh}_3$. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum shows the presence of four chemically inequivalent P atoms, as expected for the proposed stoichiometry and showing that two PPh_3 ligands have replaced two NCMe groups. Moreover, the resonance located at 14.37 ppm provides additional evidence for the presence of the free ylide group $-\text{C}(\text{O})-\text{C}(\text{H})=\text{PPh}_3$.

Synthesis of heterobimetallic complexes

We have also attempted the synthesis of bimetallic derivatives through two different methods. The first one is the reaction of the phosphonium-containing complexes **3–7** with (acac)AuPPh₃ (a method that had proved to be very efficient in palladium complexes)⁴ and the second one is the reaction of the ylide complexes **8** and **9** with ClAu(tht). To our surprise, the reactivity of **3–7** with (acac)AuPPh₃ did not give the expected results, and very complex mixtures of products were obtained.

The reactivity of **8** and **9** with ClAu(tht) (1 : 1 molar ratio) was more successful, and the heterodinuclear complexes $[\text{Pt}\{C_6H_4-2-PPh_2C(\text{H})COCH(\text{AuCl})PPh_3\}(\text{dppe})](\text{ClO}_4)$, **10**, and $[\text{Pt}\{C_6H_4-2-PPh_2C(\text{H})COCH(\text{AuCl})PPh_3\}(\text{PPh}_3)_2](\text{ClO}_4)$, **11**, were obtained (see Scheme 2). These complexes show correct elemental analyses and mass spectra for the proposed stoichiometries.

The IR spectra of **10** and **11** show the carbonyl stretch at 1621 (**10**) and at 1631 cm^{-1} (**11**), that is, shifted to higher energies when compared with the respective starting compounds **8** and **9**, and slightly shifted to lower energies when compared with the parent phosphonium derivatives **6** and **4**, respectively (although in the case of **4** this is not rigorous, since they do not have the same ancillary ligands). Thus, we have the sequence $\nu(\text{CO}, \text{ phosphonium}) > \nu(\text{CO}, \text{ C-bonded ylide}) > \nu(\text{CO}, \text{ free ylide})$. This trend has already been observed in similar situations.^{6,44} The presence of the [Au–Cl] fragment can be clearly inferred from the observation

in the IR spectra of the $\nu(\text{Au–Cl})$ stretch at 340 (**10**) and at 329 cm^{-1} (**11**), the typical region for the Cl trans to C(ylide).⁶ The ^1H and $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of **10** and **11** show the expected changes for the new stereochemistry. The resonances at 13.60 (**8**) or 14.37 ppm (**9**) in ^{31}P have moved to 25.49 (**10**) and 27.12 ppm (**11**), respectively, suggesting the C-bonding to the [AuCl] fragment. Moreover, and this fact was somewhat expected, complexes **10** and **11** have been obtained as single diastereoisomers, in spite of the presence of two chiral centers (one ylidic carbon C-bonded to platinum and one ylidic carbon C-bonded to gold). In fact, only one set of signals is observed in the NMR spectra (within the detection limits of the spectrometer), suggesting the presence of only one diastereoisomer. This behavior has already been observed in gold⁶ complexes with the bis-ylide $\text{Ph}_3\text{P}=\text{C}(\text{H})-\text{C}(\text{O})-\text{C}(\text{H})=\text{PPh}_3$, in palladium complexes with the same bis-ylide², and in heterodinuclear PdAu and trinuclear Pd₂Hg complexes with the C,C,C-terdentate orthometallated ligand $C_6H_4-2-PPh_2C(\text{H})COCH(\text{ML}_n)\text{PPh}_3$.⁴ According to these precedents, we can propose that the absolute configurations of the diastereoisomers obtained in **10** and **11** are the *meso* forms ($R_{\text{C-Pd}}S_{\text{C-Au}}/S_{\text{C-Pd}}R_{\text{C-Au}}$).

Conclusions

In conclusion, the reactivity of PtCl_2 or $\text{PtCl}_2(\text{NCR})_2$ with the phosphonium ylide $[\text{Ph}_3\text{P}=\text{C}(\text{H})\text{COCH}_2\text{PPh}_3]^+$ allows the synthesis of two types of derivatives: the C-bonded complex (**1**) and new cycloplatinated compounds derived from C–H bond activation (**2a–d**). The reactivity of **2a–d** produces cationic complexes containing the orthometallated C,C-chelating ligand $[C_6H_4-2-PPh_2C(\text{H})COCH_2PPh_3]$ (**3–7**) which, in turn, can be deprotonated to give Pt^{II} derivatives with the anionic ligand $[C_6H_4-2-PPh_2C(\text{H})COCH=PPh_3]^-$ (**8, 9**). The latter are adequate starting materials for the synthesis of bimetallic species (**10, 11**) with the C,C,C-terdentate ligand $[C_6H_4-2-PPh_2C(\text{H})COCHPPh_3]^-$.

Experimental

Caution! Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of these materials should be prepared and they should be handled with great caution. See ref. 45.

General procedures

Solvents were dried and distilled under nitrogen before use: diethyl ether and tetrahydrofuran over benzophenone ketyl, dichloromethane and chloroform over P_2O_5 , acetonitrile over CaH₂, methanol over magnesium and *n*-hexane and toluene over sodium. Elemental analyses were carried out on a Perkin–Elmer 240-B microanalyser. Infrared spectra ($4000\text{--}200\text{ cm}^{-1}$) were recorded on a Perkin–Elmer 883 infrared spectrophotometer from nujol mulls between polyethylene sheets. ^1H (300.13 MHz), $^{13}\text{C}\{^1\text{H}\}$ (75.47 MHz) and $^{31}\text{P}\{^1\text{H}\}$ (121.49 MHz) NMR spectra were recorded in CDCl_3 or CD_2Cl_2 solutions at room temperature (unless otherwise stated) on a Bruker ARX-300 spectrometer; ^1H and $^{13}\text{C}\{^1\text{H}\}$ were referenced using the solvent signal as internal standard and $^{31}\text{P}\{^1\text{H}\}$ was externally referenced to H_3PO_4 (85%). Mass spectra (positive ion FAB) were recorded on a VG Autospec spectrometer from CH_2Cl_2 solutions. The starting compound $[\text{Ph}_3\text{P}=\text{C}(\text{H})\text{C}(\text{O})\text{CH}_2\text{PPh}_3](\text{ClO}_4)$ was prepared according to published methods.⁶

Syntheses

trans- $[\text{PtCl}_2(\text{NCPh})\{C(\text{H})\text{PPh}_3-\text{C}(\text{O})\text{CH}_2\text{PPh}_3\}](\text{ClO}_4)$,

1. To a solution of $\text{PtCl}_2(\text{PhCN})_2$ (0.690 g, 1.47 mmol) in 30 mL of CHCl_3 , the phosphonium ylide salt $[\text{Ph}_3\text{P}=\text{C}(\text{H})\text{COCH}_2\text{PPh}_3](\text{ClO}_4)$ (1.00 g, 1.47 mmol) was added and the resulting solution was refluxed for 5 h. After

the reaction time, the solvent was evaporated to dryness and the residue was treated with Et₂O (20 mL), giving **1** as a pale yellow solid, which was filtered and air dried. Obtained: 1.40 g (91% yield).

[Pt(μ-Cl){C₆H₄-2-PPh₂C(H)COCH₂PPh₃}]₂(ClO₄)₂, **2a-d**.

Method (a). Finely ground PtCl₂ (0.090 g, 0.36 mmol) was suspended in 50 mL of CH₂Cl₂. To this suspension [Ph₃P=C(H)COCH₂PPh₃](ClO₄) (0.500 g, 0.73 mmol) was added and this mixture was stirred at room temperature for 4 days. The resulting brown suspension was filtered, the filtrate evaporated to dryness and the residue treated with PrⁱOH (25 mL), giving a mixture of the *syn* (**2a**, **2b**) and *anti* (**2c**, **2d**) complexes as a cream solid, which was filtered, washed with additional PrⁱOH (10 mL) and *n*-hexane (20 mL). Obtained: 0.27 g (82% yield). The molar ratios **2a** : **2b** : **2c** : **2d** may be different in different preparations, but the *anti* derivatives always appear as traces. Usually the molar ratio of the *syn* isomers is major : minor = 2 : 1.

Method (b) To a solution of PtCl₂(NCMe)₂ (1.00 g, 2.64 mmol) in 25 mL of 2-methoxyethanol, [Ph₃P=C(H)COCH₂PPh₃](ClO₄) (1.79 g, 2.64 mmol) was added and the resulting suspension was refluxed. After a short induction period, the initial suspension dissolved almost completely and the color of the solution changed gradually to off-white (30 min). An off-white solid precipitated during the remaining reaction time (5 h). This solid was filtered, washed with PrⁱOH (10 mL) and *n*-hexane (15 mL), air dried and identified as a mixture of the *syn* (**2a**) and the *anti* (**2c**, **2d**) isomers (molar ratio *anti* : *syn* = 2.77 : 1; *anti* isomers: molar ratio major : minor = 1.37 : 1). Obtained: 1.39 g (58.5% yield). Further evaporation of the alcoholic solution to a small volume (5 mL) and addition of PrⁱOH (15 mL) yielded a second crop of **2c**, **2d** (0.400 g, 16.7% yield). Total yield: 75.2%.

Anal. calcd. for C₇₈H₆₄Cl₄O₁₀P₄Pt₂: C, 51.55; H, 3.55. Found: C, 51.73; H, 3.98. IR (cm⁻¹): 1652 (ν_{CO}), 283 (ν_{Pt-Cl}). [Pt{C₆H₄-2-PPh₂C(H)COCH₂PPh₃}(phen)](ClO₄)₂, **7**. In a similar way to that described for **6**, **2** (0.21 g, 0.11 mmol) reacts with AgClO₄ (0.05 g, 0.23 mmol) and phen (0.04 g, 0.23 mmol) to give **7** as a white solid. Obtained: 0.23 g (85% yield). Complex **7** was recrystallized from a CH₂Cl₂-Et₂O (1 : 10) mixture, which gave **7**·CH₂Cl₂ as white crystals, which were used for analytical and spectroscopic purposes. The amount of CH₂Cl₂ was determined by ¹H NMR.

Anal. calcd. for C₅₀H₄₀Cl₂N₂O₉P₂Pt·CH₂Cl₂: C, 50.46; H, 3.42; N, 2.26. Found: C, 50.61; H, 3.54; N, 2.58. IR (cm⁻¹): 1657 (ν_{CO}). FAB-MS [*m/z*, (%): 1053 (13%) [M - ClO₄]⁺, 952 (100%) [M - 2 ClO₄ - H]⁺. ¹H NMR (CDCl₃): δ 10.09 (d, 1H, H_α, phen, ³J_{αβ} = 4.5 Hz), 9.24 (d, 1H, H_ω, phen, ³J_{ωβ} = 5.1 Hz), 8.70 (d, 1H, H_γ, phen, ³J_{γβ} = 8.4 Hz), 8.56 (d, 1H, H_{γ'}, phen, ³J_{γ'β} = 8.4 Hz), 8.15 (dd, 1H, H_β, phen), 8.01 (d, 1H, H_β, phen, ³J_{ββ'} = 9 Hz), 7.99 (dd, 1H, H_β, phen), 7.95 (d, 1H, H_β, phen), 7.88–7.26 (m, 29 H, Ph), 5.80 (s, 1H, CHPt), 5.47 (dd, 1H, CH₂P, ²J_{H-H} = 18.00 Hz, ²J_{P-H} = 12.30 Hz), 5.15 (dd, 1H, CH₂P, ²J_{P-H} = 12 Hz). ³¹P{¹H} NMR (CDCl₃): δ 26.55 (d, PPh₂ in ring, ⁴J_{P-P} = 10 Hz), 20.79 (d, CH₂PPh₃).

[Pt{C₆H₄-2-PPh₂C(H)COC(H)2PPh₃}(dppe)](ClO₄), **8**. To a suspension of **6** (0.20 g, 0.14 mmol) in THF (20 mL) was added an excess of NaH (0.10 g, 4.16 mmol). This mixture was stirred at room temperature for 10 h. During this time, a slow evolution of gas (H₂) was observed, and the color of the suspension changed gradually from white to yellow. After the reaction time, the suspension was filtered and the solution was evaporated to dryness, extracted with CH₂Cl₂ (20 mL) and filtered again. The resulting solution was evaporated to dryness and the oily residue was treated with Et₂O (15 mL), giving **8** as a yellow solid. Obtained: 0.11 g (63.9% yield). Due to the presence of traces of the bis-oxide P(O)Ph₂CH₂CH₂P(O)Ph₂, complex **8** was recrystallized from CH₂Cl₂-*n*-hexane to give **8**·2 CH₂Cl₂ as yellow crystals, which were used for analytical and spectroscopic purposes.

Anal. calcd. for C₆₅H₅₅ClO₅P₄Pt·2 CH₂Cl₂: C, 55.86; H, 4.13. Found: C, 56.16; H, 4.84. IR (cm⁻¹): 1529 (ν_{CO}). FAB-MS [*m/z*, (%): 1170 (85%) [M - ClO₄]⁺. ¹H NMR (CD₂Cl₂): δ 7.91–6.88 (m, 49 H, Ph), 4.15 (t, CHPt, 1H, ²J_{P-H} = ³J_{P-H} = 7.8 Hz, ²J_{Pt-H} = 69 Hz), 3.09 [d, -C(H)=P, 1H, ²J_{P-H} = 25.2 Hz], 2.47–1.82 (m, 4 H, CH₂-dppe). ³¹P{¹H} NMR (CD₂Cl₂): δ 45.28 (d, 1P, PPh₂-*trans*-C_{ylide}, ³J_{P-P} = 17.7 Hz, ¹J_{P-Pt} = 2688 Hz), 44.41 (d, 1P, PPh₂-*trans*-C_{aryl},

³J_{P-P} = 36.3 Hz, ¹J_{P-Pt} = 1856 Hz), 30.87 (ddd, 1P, PPh₂ in ring, ⁴J_{P-P} = 7.2 Hz), 13.60 (d, 1P, CH=PPh₃).

[Pt{C₆H₄-2-PPh₂C(H)COC(H)2PPh₃}(PPh₃)₂](ClO₄), **9**. To a THF suspension (20 mL) of **4** (0.174 g, 0.16 mmol) was added excess of PPh₃ (0.130 g, 0.49 mmol). The suspension gradually dissolved and to the resulting solution NaH (0.10 g, excess) was added. This mixture was stirred at room temperature overnight and then filtered. The filtrate was evaporated to dryness, extracted with CH₂Cl₂ (15 mL), filtered again and the resulting solution evaporated to dryness to give **9** as a white solid, which was collected with Et₂O (20 mL) and air dried. Obtained: 0.130 g (58% yield).

Anal. calcd. for C₇₅H₆₁ClO₅P₄Pt: C, 64.49; H, 4.40. Found: C, 64.86; H, 4.37. IR (cm⁻¹): 1531 (ν_{CO}). FAB-MS [*m/z*, (%): 1297 (10%) [M - ClO₄]⁺, 1035 (100%) [M - ClO₄ - PPh₃]⁺. ¹H NMR (CDCl₃): δ 7.94–6.70 (m, 59 H, Ph + C₆H₄), 3.89 [d, -C(H)=P, 1H, ²J_{P-H} = 26.1 Hz], 3.62 (m, CHPt, 1H, ²J_{Pt-H} = 64 Hz). ³¹P{¹H} NMR (CDCl₃): δ 30.70 (dd, 1P, PPh₂ in ring, ³J_{P-P} = 32.7 Hz, ³J_{P-P} = 17.5 Hz), 26.86 (t, 1P, PPh₃-*trans*-C_{ylide}, ³J_{P-P} = ²J_{P-P} = 17.5 Hz, ¹J_{P-Pt} = 2576 Hz), 22.90 (dd, 1P, PPh₃-*trans*-C_{aryl}, ¹J_{P-Pt} = 1698 Hz), 14.37 (s, 1P, CH=PPh₃).

[Pt{C₆H₄-2-PPh₂C(H)COC(H)(AuCl)PPh₃}(dppe)](ClO₄), **10**. To a CH₂Cl₂ solution (15 mL) of complex **8** (0.074 g, 0.058 mmol) ClAu(tht) (0.018 g, 0.058 mmol) was added and the resulting solution was stirred at room temperature for 15 min. Evaporation of the solvent to dryness and treatment of the white residue with Et₂O (10 mL) gave **10** as a white solid. Obtained: 0.059 g (68% yield). Due to a small amount of decomposition products, complex **10** was recrystallized from CH₂Cl₂-*n*-hexane to give white crystals of **10**·2CH₂Cl₂, which were used for analytical and spectroscopic purposes.

Anal. calcd. for C₆₅H₅₅AuCl₂O₅P₄Pt·2 CH₂Cl₂: C, 48.10; H, 3.55. Found: C, 48.04; H, 3.87. IR (cm⁻¹): 1621 (ν_{CO}), 340 (ν_{Au-Cl}). FAB-MS [*m/z*, (%): 1403 (35%) [M - ClO₄]⁺, 1170 (15%) [M - ClO₄ - AuCl]⁺. ¹H NMR (CDCl₃): δ 7.90–6.64 (m, 49 H, Ph + C₆H₄), 5.18 (td, CHPt, 1H, ²J_{P-H} = ³J_{P-H} = 8 Hz, ³J_{P-H} = 1.5 Hz, ²J_{Pt-H} = 55 Hz), 2.77 (s, br, 1H, CHAu), 2.52–1.99 (m, 4 H, CH₂-dppe). ³¹P{¹H} NMR (CDCl₃): δ 45.63 (d, 1P, PPh₂-*trans*-C_{ylide}, ³J_{P-P} = 17.9 Hz, ¹J_{P-Pt} = 2933 Hz), 41.02 (d, 1P, PPh₂-*trans*-C_{aryl}, ³J_{P-P} = 30.5 Hz, ¹J_{P-Pt} = 1856 Hz), 27.98 (ddd, 1P, PPh₂ in ring, ⁴J_{P-P} = 13.4 Hz), 25.49 [d, 1P, CH(AuCl)PPh₃].

[Pt{C₆H₄-2-PPh₂C(H)COC(H)(AuCl)PPh₃}(PPh₃)₂](ClO₄), **11**. Complex **11** was obtained following the same method as that described for **10**: complex **9** (0.108 g, 0.077 mmol) and ClAu(tht) (0.025 g, 0.077 mmol) reacted in CH₂Cl₂ (10 mL) to give **11** as a white solid. Obtained: 0.086 g (69% yield). Complex **11** was recrystallized from CH₂Cl₂-*n*-hexane, giving white crystals of **11**·0.5 CH₂Cl₂, which were used for analytical and spectroscopic purposes.

Anal. calcd. for C₇₅H₆₁AuCl₂O₅P₄Pt·0.5 CH₂Cl₂: C, 54.25; H, 3.74. Found: C, 54.19; H, 3.86. IR (cm⁻¹): 1631 (ν_{CO}), 329 (ν_{Au-Cl}). FAB-MS [*m/z*, (%): 1529 (5%) [M - ClO₄]⁺, 1267 (20%) [M - ClO₄ - PPh₃]⁺, 1035 (20%) [M - ClO₄ - PPh₃ - AuCl]⁺. ¹H NMR (CDCl₃): δ 7.79–6.47 (m, 59 H, Ph + C₆H₄), 4.55 (t, CHPt, 1H, ³J_{P-H} = ²J_{P-H} = 9.3 Hz, ²J_{Pt-H} = 88 Hz), 2.88 (s, br, 1H, CHAu), ³¹P{¹H} NMR (CDCl₃): δ 29.61 (ddd, 1P, PPh₂ in ring, ³J_{P-P} = 32.2 Hz, ³J_{P-P} = 17.7 Hz, ⁴J_{P-P} = 10 Hz), 27.12 [d, 1P, CH(AuCl)PPh₃], 22.51 (t, 1P, PPh₃-*trans*-C_{ylide}, ³J_{P-P} = ²J_{P-P} = 17.5 Hz, ¹J_{P-Pt} = 2615 Hz), 19.14 (dd, 1P, PPh₃-*trans*-C_{aryl}, ¹J_{P-Pt} = 1644 Hz).
