

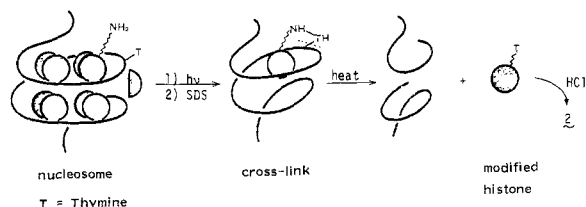

Scheme I. Schematic Representation of the Proposed Mechanism for Photo-Cross-Linking in Nucleosome

peak corresponding to **2** gave a pure product whose chromatographic behaviors,^{7a,15} UV spectrum,^{7a} and 400-MHz ¹H NMR⁸ are identical with those of the authentic sample obtained from the model experiment. The contents of thymine-lysine adduct **2** were directly determined by HPLC analysis of the acid hydrolysates of UV-irradiated nucleohistone under various conditions. The amount of **2** in UV-irradiated nucleohistone at pH 10.5 increased proportionally with increasing irradiation time within 40 min, and further irradiation no more increased the yield of **2** significantly (Table I). This may reflect that the lysine ϵ -amino group of intimate association with thymine in DNA is primarily responsible for the formation of **2**.¹⁶ Irradiation at pH 7.5 proceeded less efficiently, and the yield of **2** increased with increasing pH.

In order to confirm whether a similar photo-cross-linking is feasible in irradiation of nuclei, we examined the irradiation of chicken erythrocyte nuclei¹⁷ (0.1 mg/mL) at 0 °C in the same buffer at pH 9.5. After being heated at 70 °C, the photolysate was hydrolyzed (6 N HCl, 110 °C) and then analyzed by amino acid analyzer to reveal again the presence of **2** in the hydrolysate. Control experiments without irradiation or irradiation with light through a Pyrex filter (>280 nm) never produced **2** under the conditions. Thus, we were able to confirm that irradiation of DNA-protein systems in calf thymus nucleohistone or chicken erythrocyte nuclei with 254-nm light followed by acid hydrolysis leads ultimately to the formation of **2**. However, we are not confident whether the adduct formation is resulted solely from the photoreaction of specific DNA-histone systems because of the presence of other proteins in nucleohistone used.¹⁸

It has previously been reported that UV irradiation of chromatin produces DNA-histone adducts.^{4,19} Kunkel and Martinson²⁰ have observed that a considerable amount of reversal of DNA-histone cross-links occurred in irradiation of calf thymus nuclei with light between 230 and 290 nm, i.e., the histones cross-linked to DNA are released by chemical hydrolysis or upon rechromatography on Sepharose column, while the chemical nature of the reversibility and the sites of binding have been totally unknown.²¹ By knowing the chemical reactivity of **3** and by the confirmation of **2** in UV-irradiated DNA-protein systems, it seems probable that the apparent reversibility is due to the cross-links of the lysine ϵ -amino groups to thymine in DNA as outlined in eq 1. Thus, the photoexcited state of thymine N(3) monoanion^{7b} in DNA would react with neighboring lysine ϵ -amino groups of histones to result in the formation of DNA-histone adducts which on subsequent

heating release free histones containing partially modified lysine residues as illustrated in Scheme I. We have already demonstrated that irradiation of DNA with alkylamines and subsequent heating of the photolysate at an alkaline pH induce DNA strand scission at the sites of reacting thymine.^{7b,23} It is therefore highly probable that DNA in UV-irradiated chromatin may suffer strand scission at the sites of reacting thymine upon heating under the slightly alkaline conditions, although the mechanistic details should await further studies using each of the purified histone-DNA adducts.

In conclusion, the present work has demonstrated an important role of thymine-lysine photoreaction in the photo-cross-linking of proteins to DNA. Since the thymine-lysine photoadduct **2** is readily detectable by HPLC and amino acid analyzer, irradiation with 254-nm light may provide a useful means for probing specific interaction sites between thymine and lysine residues in DNA-protein complexes. Furthermore, such type of photo-cross-linking may be relevant to the UV-induced damage on DNA in cells.

Cobalt-Catalyzed Cocyclizations of Isocyanatoalkynes: A Regiocontrolled Entry into 5-Indolizinones. Application to the Total Synthesis of Camptothecin

Richard A. Earl and K. Peter C. Vollhardt*

Department of Chemistry, University of California and the Materials and Molecular Research Division Lawrence Berkeley Laboratory, Berkeley, California 94720

Received July 11, 1983

Pyridones, particularly those containing bridgehead nitrogen, constitute useful moieties in heterocycle construction of value in alkaloid¹ and drug² synthesis. We report the cobalt-catalyzed [2 + 2 + 2] cycloaddition of the novel 5-isocyanatoalkynes **1** to alkynes, providing a chemo- and regioselective entry into the class of functionalized 2,3-dihydro-5(1*H*)-indolizinones. The method is readily applied to a total synthesis of the antitumor alkaloid camptothecin.³

The requisite starting material 5-isocyanato-1-pentyne (**1a**) [bp 85 °C (70 torr)], is available⁴ from 5-hexynoic acid via acid chloride formation [(COCl)₂, C₆H₆, DMF (catalyst), 25–35 °C, 82%]⁵ and Curtius rearrangement (NaN₃, CH₃CN, Δ , 1 h, 74%), whereas **1b** [bp 80–85 °C (0.2 torr)] is prepared from 3-carbomethoxypropanoyl chloride⁶ according to Scheme I.

Table I. Results of the Cocyclization of 1 with Alkynes

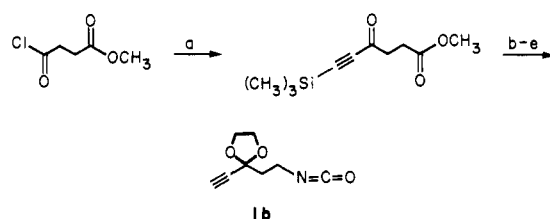

entry	isocyanato-alkyne	R	R'	% yield of 3 (mp, °C)	% yield of 4 (mp, °C)
1	1a	(CH ₃) ₃ Si	(CH ₃) ₃ Si	72 (117–119)	
2	1a	<i>n</i> -Pr	(CH ₃) ₃ Si	68 (64–66)	5 (115–120)
3	1a		(CH ₃) ₃ Si	76 (150–152)	
4	1a	<i>t</i> -Bu	(CH ₃) ₃ Si ^a	17 (79–81)	<1
5	1a		Et	41 (oil)	31 (oil)
6	1b	(CH ₃) ₃ Si	(CH ₃) ₃ Si	68 (134–135)	
7	1b	<i>n</i> -Pr	(CH ₃) ₃ Si	60 (87–89)	3 (oil)
8	1b	<i>n</i> -Pr	CH ₂ OSi(<i>t</i> -Bu)(C ₆ H ₅) ₂	20 (165–167) ^b	18 (oil)
9	1b	CH ₃	CO ₂ Et	14 (108–110; lit. ⁵ 110–112)	17 (96–97)

^a Products were isolated in their protodesilylated form after chromatography on silica. ^b Correlated with the aldehyde precursor to 6 (Scheme II).

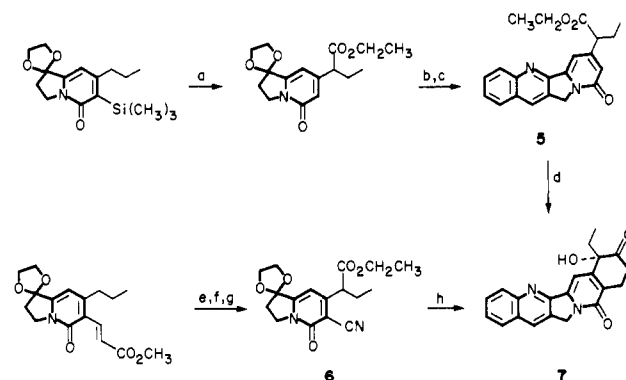

Cocyclization of **1** with a variety of alkynes in the presence of catalytic η^5 -C₅H₅Co(CO)₂ (*m*-xylene, Δ , *h* ν , 3–5 h) gave the results shown in Table I.⁴ The regiochemical assignments were based on comparison of the protodesilylated analogues [CF₃CO₂H, C₆H₆ or (CH₃)₄N⁺F[−]·3H₂O, DMSO, 1 h, 60–80 °C] with known compounds.^{5,9} One notes that good chemo- and regioselectivity¹⁰ is achievable by the use of trimethylsilylated alkynes, the silyl group emerging preferentially α to the amide linkage, even when pitted against *tert*-butyl (entry 4), pointing to the operation of a stereoelectronic effect which appears peculiar for silicon.¹¹ The thus formed rare silylpyridones¹² are very effective substrates for selective¹³ electrophilic 6-halodesilylations⁴ (Br₂ or ICl, CH₂Cl₂, 0 °C) to give **3a** [R = *n*-Pr, R' = Br, 73%, mp 107–109 °C; R

= *n*-Pr, R' = I, 66%, mp 86–87 °C; R = CH₃CH₂(CO₂C₂H₄), R' = Br, 70%, mp 113–115 °C; R = CH₃CH₂(CO₂C₂H₄), R' = I, 94%, mp 101–104 °C; R = (CH₃)₃Si, R' = I, 90%, mp 167–168.5 °C or **3b** [R = *n*-Pr, R' = I, 93%, mp 114–116 °C; R = (CH₃)₃Si, R' = I, 86%, mp 144–145 °C]. The iodides undergo highly efficient palladium-catalyzed coupling reactions⁴

t-CH=CHC₆H₅, 69%, mp 99–102 °C).

To demonstrate the utility of these transformations in natural product construction two formal total syntheses of camptothecin (7), a molecule of renewed recent interest,^{16,17} were executed⁴ as in Scheme II in respectable yield²¹ through the intermediacy of the two key intermediates 5 and 6.

The present work offers a uniquely versatile way to assemble annulated pyridones with extensive control of their substitution pattern,¹³ by using a transition metal as a template on which to simultaneously generate three new bonds. This approach should surpass the flexibility attained by conventional Diels–Alder routes.²²

Finally, we note that another catalyst reported to catalyze the formation of 2-pyridones from alkynes and isocyanates, bis(η⁴-cyclooctadiene)nickel,²³ is unsuccessful in our systems and very likely operates through an alternative mechanism.¹¹

Iminium Ion and Acyliminium Ion Initiated Cyclizations of Vinylsilanes. Regiocontrolled Construction of Unsaturated Azacyclics

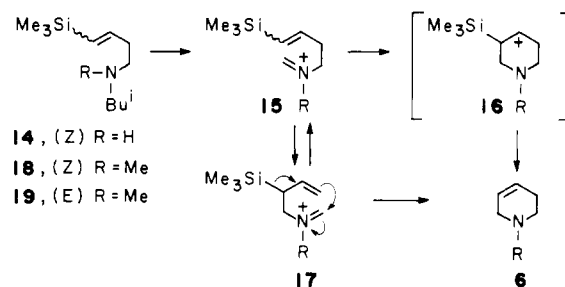

Larry E. Overman,* Thomas C. Malone, and G. Patrick Meier¹

Department of Chemistry, University of California
Irvine, California 92717

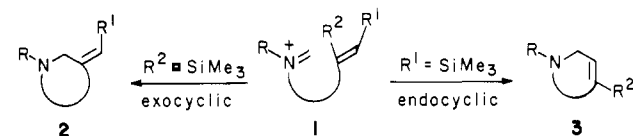

Received July 27, 1983

Vinylsilanes are rapidly becoming important terminators for cationic cyclizations.² We have described^{2a,b} a general stereocontrolled synthesis of alkylidene azacyclics by the intramolecular reaction of vinylsilanes with iminium ions (1 → 2). During the course of these studies, we became interested in whether these weakly reactive cyclization components would also participate in

Scheme I

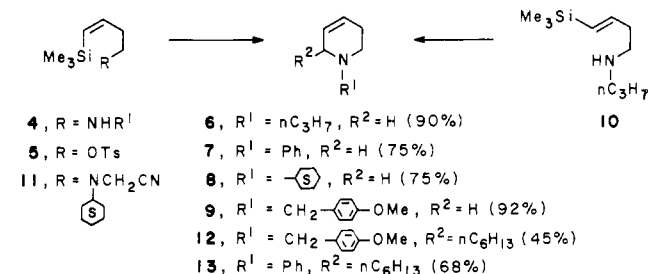

ring closures that are endocyclic³ with respect to the vinylsilane terminator (1 → 3). In this communication, we report that such

cyclizations do occur readily and provide a useful new method for the regiocontrolled assembly of unsaturated azacyclic systems.

We initially explored cyclizations to form tetrahydropyridines. The starting (Z)-4-(trimethylsilyl)-3-butenamines (4)⁴ were prepared by aminolysis (excess amine, 25–80 °C) of readily available tosylate 5.^{4,5} Reactions of 4 with excess paraformaldehyde occurred in refluxing acetonitrile in the presence of 0.95 equiv of camphorsulfonic acid to give 1,2,5,6-tetrahydropyridines 6–9⁴ in excellent yields. Alternatively, a (cyanomethyl)amine⁶

could be employed and the cyclization (e.g., 11 → 8, 56%) accomplished by treatment with silver trifluoroacetate (1 equiv, 100 °C). The stereochemistry of the vinylsilane terminator was not critical, since the (E)-vinylsilane 10^{4,7,8} was converted to 6 in 73% yield when treated under similar conditions with paraformaldehyde and acid. Other aldehydes could also be employed. For example, amines 4 (R¹ = Ph and p-methoxybenzyl) were cleanly cyclized at 120 °C with heptanal (3 equiv) and camphorsulfonic acid (0.95 equiv) to yield the 2-substituted tetrahydropyridines 12⁴ and 13.⁴

The 1,2,5,6-tetrahydropyridine ring is found in several natural products and numerous pharmacologically active materials.⁹ This
