Abstract

Twelve diorganotin(IV) complexes of 2-quinaldate $\text{R}_2\text{Sn}(2\text{-quin})_2$ and $\text{R}_2\text{SnCl}(2\text{-quin})$ have been synthesized by dealkylation reactions of 2-quinaldic acid (2-quinH) with $(\text{R}_3\text{Sn})_2\text{O}$ ($\text{R} = \text{PhCH}_2$ **1**, $2\text{-ClC}_6\text{H}_4\text{CH}_2$ **2**, $2\text{-FC}_6\text{H}_4\text{CH}_2$ **3**, $4\text{-FC}_6\text{H}_4\text{CH}_2$ **4**, $4\text{-CNC}_6\text{H}_4\text{CH}_2$ **5**, Ph **6**, $2,4\text{-Cl}_2\text{C}_6\text{H}_3\text{CH}_2$ **7**) and R_3SnCl ($\text{R} = 2\text{-ClC}_6\text{H}_4\text{CH}_2$ **8**, $4\text{-ClC}_6\text{H}_4\text{CH}_2$ **9**, $2\text{-FC}_6\text{H}_4\text{CH}_2$ **10**, $4\text{-FC}_6\text{H}_4\text{CH}_2$ **11**, PhCH₂ **12**), and all the complexes have been characterized by elemental analysis, IR and multinuclear NMR (^1H , ^{13}C , ^{119}Sn) spectroscopies. The structures of $(4\text{-FC}_6\text{H}_4\text{CH}_2)_2\text{Sn}(2\text{-quin})_2 \cdot 2\text{CH}_3\text{CN}$ (**4**) and $\{[(2\text{-ClC}_6\text{H}_4\text{CH}_2)_2\text{Sn}(2\text{-quin})\text{Cl}]_2 \cdot \text{CH}_3\text{OH}\}_n$ (**8**) have been determined by X-ray diffraction. Studies show that complex **4** is a monomer with the central tin atom six-coordinated in a skew-trapezoidal-bipyramidal geometry and complex **8** is a one-dimensional polymer with the tin atom six-coordinated. Studies also show that the nitrogen atoms of the 2-quin ligand are coordinating to the tin atoms for all of the 12 complexes.

1. Introduction

Organotin(IV) complexes are widely used as biocides, fungicides and as homogeneous catalysts in industry [1–5]. Recently, pharmaceutical properties of organotin complexes with carboxylic acid have been investigated for their antitumor activity [6–9]. In general, the biocidal activity of organotin complexes is greatly influenced by the structure of the complex and the coordination number at the tin atoms [8–12]. Previous papers [5,13–15] have reported the synthesis and X-ray crystal structure determinations of several organotin complexes with carboxylic acids in which the R' group has an additional

potential donor atom (e.g., N, O and S) available for coordinating to tin, and that have led to new structural modes of the organotin derivatives. We have previously reported several unexpected products of organotin(IV) complexes with pyridinylcarboxylic acids [14,15], which can be assigned to dealkylation reactions as can be seen in the literature [16–19]. As an extension of this study, we synthesized another 12 diorganotin complexes of 2-quinaldate by two quite different methods. Studies show that whichever reaction we selected the final products are diorganotin complexes of 2-quinaldate, which strongly indicates that the steric bulk of the ligand 2-quin plays a significant role in controlling the coordination geometry at tin regardless of the nature of the tin-bound R groups. All the complexes have been characterized by elemental analyses, IR and NMR (^1H , ^{13}C

2. Experimental

2.1. Materials and methods

Triorganotin(IV) chloride and bis(triorganotin)(IV) oxide were prepared by the methods described in the literature [20]. The melting points were obtained with Kofler micro melting point apparatus and uncorrected. IR spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs and sodium chloride optics. ^1H , ^{13}C and ^{119}Sn NMR spectra were recorded on a Mercury Plus-400 NMR spectrometer, chemical shifts were given in ppm relative to Me_4Si and Me_4Sn in CDCl_3 solvent. Elemental analyses were performed in a PE-2400 II elemental analyzer.

2.3. X-ray crystallography

Crystallographic data and refinement details are given in Table 1. All X-ray crystallographic data were collected on a Bruker smart-1000 CCD diffractometer with graphite monochromated Mo Kα (0.71073 Å) radiation and the φ-ω scan technique. The structures were solved by direct method and difference Fourier map using SHELXL-97 program, and refined by full-matrix least-squares on *F*². All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located at calculated positions and refined isotropically.

3. Results and discussion

3.1. Syntheses

We treated (R₃Sn)₂O and 2-quinH in a 1:2 stoichiometry in benzene and hoped to get triorganotin complexes of 2-quinaldate. To our surprise, dealkylation reaction

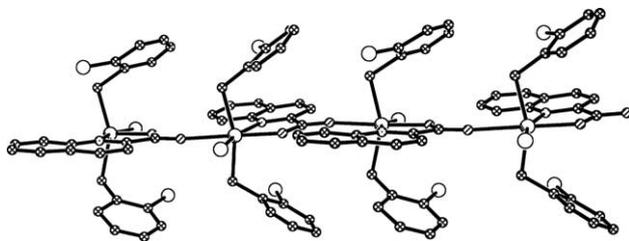

occurs and as a result we have obtained 12 diorganotin(IV) complexes of 2-quinaldate. We assumed that it may result from the steric bulk of the 2-quin ligand as have studied in the previous report [14–19], in order to confirm our assumption we have done further research by devising another reaction shown in Scheme 1. Studies show that whichever reaction we selected the final products are diorganotin complexes of 2-quinaldate, which strongly indicates that the coordination number at tin is dominated by the 2-quin ligand. And studies also show that the structure of the molecule have something to do with the reaction conditions and tin-bound R groups. The existence of H₂O or Et₃N·HCl facilitates the dealkylation reaction. Based on these studies, we raised possible mechanisms for all of the 12 complexes, which are shown in Scheme 1.

3.2. IR and NMR studies

The infrared spectra of diorganotin(IV) complexes with carboxylic acid have been recorded and some important assignments are shown above. The Δ*v* (*v*_{as}(CO₂) – *v*_s(CO₂)) value is used to determine the nature of bonding of carboxylate to tin(IV) complexes according to the previous report [21]. It is generally believed that the difference in Δ*v* between asymmetric *v*_{asym}(CO₂) and symmetric *v*_{sym}(CO₂) absorption frequencies below 200 cm⁻¹ for the bidentate carboxylate moiety, but greater than 200 cm⁻¹ for the unidentate carboxylate moiety [22]. Study shows that the values of Δ*v* of the complex **1–7** are between 265 and 348 cm⁻¹ and this strongly indicate that these complexes adopt unidentate carboxylate structure [23,24]. The value of Δ*v* of complexes **8–12** are 171–194 cm⁻¹, and this shows that complexes **8–12** adopt the bidentate carboxylate, which accords with the result of the X-ray diffraction study for complex **8**. Compared with the free ligand the new occurrence of the bands in the region of 474 and 499 cm⁻¹ for all the 12 complexes were assigned to the Sn–N vibrations, which provides prove for the existence of Sn–N bonds for all of the 12 complexes, and the bands in the region of 450 and 469 cm⁻¹ were assigned to the Sn–O vibrations according to the literature [14,15].

Chemical shifts δ(¹H) and δ(¹³C) inherent to ligand atoms and organic radicals bound to Sn in complexes **1–12** are assigned by comparison with the spectra of the free ligand, 2-quinaldic acid as well as of the complex [R₂SnCl₂(2-quin)]⁻(HNEt₃)⁺ [24]. Signal integrations indicate the stoichiometry R₂Sn(2-quin)₂ and R₂SnCl(2-quin).

The ¹H NMR of complexes **1–5**, and **7–12** show that the chemical shifts of the protons of methylene on the benzyl group exhibit signals about 2.94–3.15 ppm as single with ¹¹⁹Sn satellites, the coupling constant *J*_{Sn-H} is equal 80–89 Hz. The signals at 7.48–8.84 ppm as multiplicity for all the 12 complexes are assigned to the

3.3.1. Structures of $[(4\text{-F-PhCH}_2)_2\text{Sn}(2\text{-quin})_2] \cdot 2(\text{CH}_3\text{CN})$ (**4**) and $\{[(2\text{-Cl-PhCH}_2)_2\text{Sn}(2\text{-quin})\text{Cl}]_2 \cdot (\text{CH}_3\text{OH})\}_n$ (**8**)

Complex **4** is a monomer as can be seen in Fig. 1. In the structure of the complex, the tin atom forms four pri-

mary bonds: two to the *p*-fluorobenzyl carbon atoms, and two to the oxygen atoms of two carboxylates. In addition, there exists a coordination interaction between tin and nitrogen atoms. The Sn–N bond length 2.516(2) Å for Sn(1)–N(1) and 2.505(3) Å for Sn(1)–N(2) is similar to that of the corresponding distances found in $\text{Me}_2\text{Sn}(2\text{-quin})_2$ (2.594(3), 2.473(4) Å) and $\text{C}_2\text{Sn}(2\text{-pic})_2(\text{OH})_2 \cdot \text{MeOH}$ (2.550(3), 2.495(3) Å) [13], it is longer than that of found in $\text{Me}_2\text{Sn}(2\text{-quin})_2$ showing above, but it is much shorter than the sum of the van der Waals radii of tin and nitrogen, 3.74 Å [28]. The two 2-quin ligands are bidentate coordinating to the tin atom using one carboxylate oxygen atom and the nitrogen atom, thus providing five-membered chelate rings with bite angles of 70.26(9)° for O(1)–Sn(1)–N(1) and 70.99(8)° for O(3)–Sn(1)–N(2). Thus the geometry at tin becomes skew-trapezoidal-bipyramidal with two *p*-fluorobenzyl carbon atoms in axial sites and two oxygen atoms and two nitrogen atoms occupying the equatorial position. The sum of the angles subtended at tin atom in the trigonal plane is 359.96°, so that the Sn(1), O(1), O(3), N(1) and N(2) atoms are in the same plane, and the mean deviation for these atoms from the plane is ±0.0112 Å.

Study shows that in this complex there exists intermolecular non-bonding F···F interaction similar to that of the Cl···Cl interaction in our previous report [29]. The F···F bond distance is 2.877 Å, which is considerably shorter than the sum of the van der Waals radii of twice the fluorine atoms and should be considered as weak non-bonding interaction [28], thus the complex become a weakly-bridged one-dimensional chain polymer as can be seen in Fig. 2.

While complex **8** is a polymer with the structural unit containing two distinct tin atoms with small differences in bond lengths and bond angles as shown in Fig. 2, both of the tin atoms are six-coordinate axially by two oxygen atoms and equatorially by one chlorine atom, one nitrogen atom and two tin-bound *o*-chlorobenzyl carbon atoms. The carboxylate groups are bidentate with one each oxygen atom to the intramolecular and the intermolecular tin atoms, thus the complex becomes a one-dimensional chain polymer as shown in Fig. 3.

The Sn–O bond distances 2.097(6) Å for Sn(1)–O(1), 2.434(7) Å for Sn(1)–O(4A), 2.107(6) Å for Sn(2)–O(3) and 2.421(7) Å for Sn(2)–O(2) are similar to that of the corresponding distances found in $[\text{t}^n\text{Bu}_3\text{Sn}(\text{O-COCH}_2\text{C}_6\text{H}_5\text{N-3})]_n$ [30]. The Sn–Cl bond lengths are 2.436(3) Å for Sn(1)–Cl(1) and 2.454(3) Å for Sn(2)–Cl(2) lie in the range of the normal covalent radii 2.37–2.60 Å [31]. The bond angles 175.0(3) Å for O(1)–Sn(1)–O(4A) and 178.6(3) Å for O(3)–Sn(2)–O(2) indicate that the geometry at both tin atoms become distorted octahedral. The sum of the angles subtended at Sn(1) and Sn(2) atoms in the equatorial plane are 367° and 366.2°, respectively, which shows that the Sn(1), Cl(1), C(21), C(28) and the Sn(2), Cl(2), C(42), C(35)

atoms are almost co-planar. The mean deviations from the plane are ± 0.3259 and ± 0.3035 Å. Studies show that the dihedral angles formed by the two planes is 6.6° , and this indicates that the above eight atoms also are almost in the same plane.
