Abstract: In situ prepared Cp₂(Cl)Zr[⊕] catalyzes the formation of ortho esters from epoxy esters. Acid-sensitive α -amino and α -hydroxy acid derivatives are converted in high yield to 2,7,8-trioxabicyclo[3.2.1]octanes (ABO-esters) using this protocol. This strategy is complementary to the OBO-ester technology, and orthogonal methods for the deprotection of ABO- and OBO-esters have been developed. The syntheses of the mushroom components (*S*)- γ -hydroxyleucine lactone and (*S*)- α -vinylglycine underline the value of ABO-ester protective group strategy. Using chiral epoxy alcohol derivatives, the first convenient and general asymmetric synthesis of bicyclic ortho esters has been achieved. © 1997 Elsevier Science Ltd.

Introduction

Neutral d(0)-metallocenes of the general formula Cp₂MX₂ (M = Ti, Zr, Hf; X = CI, Br, I) represent the most extensively studied class of group IVB organometallic compounds.¹ Since the mid-1970's, considerable interest in these complexes has been nurtured by the development of many applications of Schwartz reagent (Cp₂ZrHCl) in synthetic organic chemistry.² Insertion and transmetalation reactions of organozirconocenes have been extensively investigated and utilized in synthesis. The chemistry of the related 14-electron Cp₂(R)M⁺ complexes (M = Ti, Zr) has been developed since the mid 1980's.³ Their greater reactivity can be attributed to the significantly increased Lewis acidity of the metal center. This promotes coordination and activation of various Lewis basic substrates and opens reaction pathways that are unavailable to the neutral 16-electron complexes.^{2a,4}

In prior studies, we have found that the cationic zirconocene species prepared *in situ* from organozirconocene and catalytic amounts of AgClO₄ are efficient in initiating tandem epoxide rearrangement-aldehyde addition cascades⁵ and are compatible with a wide range of functional groups in the formation of dioxolanes from epoxy esters.^{6,7,8} In the latter reactions, it is likely that dioxolenium ions **4** are formed as intermediate species preceding C,C-bond formation (Scheme 1).

Interestingly, chain extension of the epoxyester substrate from 1 to 6 provided acyloxytetrahydrofurans 7 and orthoesters 8 depending on the nature of the substituent R (Scheme 2).⁶ No transfer of the organic ligand on the zirconocene to the epoxyester substrate was noted in this reaction, and, accordingly, a catalytic protocol using 5-15 mol% of commercially available zirconocene dichloride and 1-2 mol% of AgClO₄ could be used instead. In this paper, we report on the scope of this new catalytic method for ortho ester synthesis.

Results and Discussion

Treatment of a solution of succinate **9** and 0.1 equiv of zirconocene dichloride in CH_2Cl_2 with 0.01 equiv of silver(I) perchlorate⁹ (1 mol%) at room temperature for 15 min provided the orthoester **10** in 96% yield (Scheme 3). Similarly, the chloro ester **11** was converted in 93% yield without interference by the halogen substituent in the presence of 0.01 equiv of silver(I) salt. Product formation can be explained by irreversible formation of the cationic zirconocene **14**, followed by neighboring-group assisted Lewis-acid induced opening of the epoxide to give the dialkoxycarbenium ion **16** (Figure 1). Irreversible S_N2-attack of the zirconocene-complexed alkoxide at C(6) provides an acyloxytetrahydrofuran **7**, but under kinetically controlled reaction conditions, addition at C(2) appears to be favored and leads to the 2,7,8-trioxabicyclo[3.2.1]octane skeleton **17**. Release of the cationic zirconocene complex closes the catalytic cycle.

Scheme 3

Mechanistically, this ortho ester formation is related to Corey's BF3-catalyzed rearrangement of an acyloxetane to the 2,6,7-trioxabicyclo [2.2.2]octane (OBO-ester).¹⁰ The OBO-ester **19** is derived from an oxetane **18**, and the epoxide-derived orthoester product **22** (ABO-ester) is an asymmetric isomer of this bicyclooctane motif. Both ortho esters are cleaved by exposure to mild acid followed by saponification (Scheme 4). Interestingly, there is a sufficiently high difference in the Brønsted- vs. Lewis-acid-lability of OBO-ester **19** and ABO-ester **22** to allow for an orthogonal protective group strategy. Exposure of a 1:1 mixture of **19** and **22** to 5 mol% PPTs in MeOH/H₂O (40:1) at 0 °C for 2 min led to complete cleavage of the OBO-ester, and less than 5% cleavage of the ABO-ester was observed by ¹H NMR (Scheme 5). In contrast, exposure of the mixture of **19** and **22** to 0.5 equiv of *in situ* prepared Cp₂(Cl)Zr[⊕] led to a selective rearrangement of the ABO-ester to the tetrahydrofuran **24**,⁶ without affecting the OBO-ester **19**.

Both esters 23 and 24 can be further treated with base to release the acid 20 in yields of 94% and 93%, respectively, a procedure which does not affect the remaining ortho ester derivatives 22 and 19, which were recovered in 93% and 91% yield. Similarly, selective cleavage of a mixture of 19 and ABO-ester 25 was possible in high yield. Accordingly, our ABO-ester method establishes a novel orthogonal protective group strategy for carboxylic acids. Whereas cyclic ortho esters are generally more stable than their acyclic counterparts, an orthogonal protection has not yet been achieved with purely alcohol-derived ortho esters.¹¹⁻¹⁵ The ABO-ester fills this gap in the protection strategy for the carboxyl group (Figure 2).

The mild conditions for the zirconocene-catalyzed ortho ester formation are especially useful for the formation of ortho esters of polyfunctionalized carboxylic acids. Condensation of *N*-protected glycine **27** with epoxy alcohol **28** in the presence of dicyclohexylcarbodiimide (DCC) and dimethylaminopyridine (DMAP) followed by treatment with 10 mol% of Cp₂ZrCl₂ and 2 mol% of AgClO₄ led to the amino acid ortho ester **30** (Scheme 6). More importantly, the L-serine derivative **31** did not require protection of the side-chain hydroxyl function and was converted to the analogous orthoester **32** with less than 1% overall racemization at the α -carbon as indicated by Mosher ester analysis (Scheme 6).¹⁶ This reaction scheme was readily extended to the protection of other amino acid carboxylates. Acid-sensitive functions such as the Boc-carbamate as well as silyl ethers are fully compatible with the reaction conditions (Table 1). All ABO-derivatives shown are derived from racemic epoxy alcohol, and are, accordingly, 1:1 mixtures of diastereomers at ortho ester C(1) and C(5) positions.

 Table 1.
 Preparation of amino acid ABO-esters by cationic zirconocene-catalyzed rearrangement of epoxy esters.

Ortho esters are ideal carboxyl protective groups against nucleophilic attack by hydroxide or organometallic reagents. Conversion of a carboxylate to an ortho ester is also an effective means to reduce the acidity of the α -hydrogen. These features are especially important for the manipulation of side-chain functionalized amino acid residues.¹⁶ As an illustration for the use of ABO-esters in the stereoselective manipulation of amino acid building blocks, we have developed efficient protocols for the preparation of L- γ -hydroxyleucine lactone **46** and α -vinyl glycine **48** from L-aspartic acid. For both target molecules, ortho ester **45** served as an intermediate. This compound is readily available in 63% overall yield from *N*-Cbz-protected aspartyl ester **43** (Scheme 7). Exposure of **45** to an excess of methyl Grignard reagent, followed by acidic hydrolysis of the resulting tertiary alcohol in 1 M HCl and ester saponification provided the γ -lactone **46** in 48% yield. γ -Hydroxyleucine **46** is a component of toxins of the green death-cap mushroom *Amanito phalloides*. Previously this compound has been prepared by photochlorination of leucine,¹⁷ and our route offers improved ease of access and flexibility for variation of γ -alkyl substituents.

Scheme 7

 α -Vinylglycine is also a mushroom component and has been used as a mechanism-based enzyme inhibitor.¹⁸ Previous asymmetric syntheses of this non-proteinogenic amino acid have started from methionine,¹⁹ glutamic acid,^{20,21} serine,²² homoserine,^{23,24} D-mannitol,²⁵ and cyclo(valylglycine)²⁶ or used enzymatic resolution.¹⁸ Reduction of the aspartate derived ortho ester **45** with LiBH₄, followed by Grieco-elimination²⁷ provided the fully protected vinylglycine building block **47**. As expected, ortho ester **47** does not exhibit the well-known tendency of vinylglycine for migration of the double bond or racemization under basic conditions. Exposure to acidic methanol smoothly converted the ortho ester to vinylglycine methyl ester **48**. Ester **48** has been converted to vinylglycine hydrochloride (**49**) in quantitative yield in 6 N HCl,^{19a,b,20,21} suggesting that ortho ester **47** could be directly converted to optically pure **49** under these conditions.²⁸

Scheme 8

The ease of cationic zirconocene-catalyzed formation of 2,7,8-trioxabicyclo[3.2.1]octane ortho esters from amino acids also extends to other α -functionalized carboxylates. Treatment of the (*S*)-lactate derivative **50** with catalytic Cp₂ZrCl₂/AgClO₄ at 0 °C provided ortho ester **25** as a single stereoisomer in 92% yield (Scheme 9). The use of BF₃-etherate for this process generally leads to considerably lower yields: 60% of **25** were obtained at -78 °C, and higher temperatures led to extensive decomposition of starting material and ortho ester product. If desired, an increase in the reactivity of the cationic zirconocene catalyst can be achieved by substitution of the weakly co-

ordinating anion ClO₄⁻ with the "non-coordinating" tetraarylborate B(3,5-C₆H₃(CF₃)₂)₄⁻ (TFPB⁻).^{29,30} In the presence of 5 mol% of zirconocene dichloride and 2 mol% of AgTFPB,³¹ epoxy ester **50** was smoothly converted to ABO-ester **25** in 93% yield within 6 h at -78 °C. In toluene the reaction proceded somewhat more slowly, and 93% of **25** were isolated after 18 h at -78 °C. The conversions of **50** to **25** as a single isomer underline the high level of stereoselectivity in the neighbouring group assisted opening of epoxy ester shown in Figure 1 and represent the first convenient and general protocol for the asymmetric synthesis of ortho esters.^{32,33}

Conclusions

Ortho esters are among the few carboxylic acid protective groups that demonstrate a high level of stabillity toward strong nucleophiles and bases. Compared to a carboxylic acid, the ortho ester removes the acidic hydroxyl group as well as the electrophilic carbonyl function and reduces the acidity of the α -hydrogens by many orders of magnitude. Historically, a broad use of ortho esters has been complicated by the difficulty and low yields in their preparation from acids or nitriles and alcohols.^{14,15} Corey's OBO-ester protocol,¹⁰ the BF₃-etherate mediated preparation of the 2,6,7trioxabicyclo [2.2.2]octane ring system from oxetanyl esters, greatly facilitated the synthesis of ortho esters of functionalized carboxylates and stimulated their use as protective groups in organic synthesis.¹¹ The cationic zirconocene-catalyzed rearrangement of epoxy esters to give 2,7,8trioxabicyclo[3.2.1]octanes (ABO-esters) adds a new variant to this protective group strategy. We have been able to demonstrate that ABO-esters are readily obtained in very high yields from functionalized and acid-sensitive substrates using in situ prepared cationic zirconocene. Mild acid hydrolysis followed by saponification regenerates the carboxylate without epimerization of astereocenters in amino and hydroxy acids. Alcoholysis of the ortho ester leads directly to the corresponding alkyl ester. The syntheses of the mushroom components (S)-γ-hydroxyleucine lactone and (S)- α -vinylglycine demonstrate the versatility of this protocol.

In combination with the OBO-ester, the ABO-ester establishes for the first time an orthogonal protective group strategy for ortho esters. Bicyclo[3.2.1] ABO-esters are considerably more Brønsted acid-stable than the bicyclo[2.2.2] OBO-ester derivatives. In contrast, prolonged exposure of ABO-

ester to cationic zirconocene leads to a secondary rearrangement to an acyloxytetrahydrofuran, which can be further cleaved in the presence of an OBO-ester moiety. We expect that these new methods in addition to the asymmetric synthesis of chiral ABO-esters using readily available chiral epoxy alcohol derivatives will greatly stimulate further applications of bicyclic ortho esters in organic chemistry.

Experimental Section

General. Anhydrous solvents were freshly distilled from either sodium benzophenone ketyl, P2O5, or CaH2. All reactions were performed in oven-dried glassware under an argon or nitrogen atmosphere. IR spectra were recorded on an IBM IR/32 spectrophotometer. NMR spectra were recorded in CDCl₃ unless stated otherwise on a Bruker AC-300 NMR spectrometer (300 MHz for ¹H NMR and 75 MHz for ¹³C NMR) and are reported in ppm relative to tetramethylsilane (δ). Data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad), integration, and coupling constants. Mass spectra were obtained on a VG-70-70 HF. Analytical TLC used Merck silica gel 60 F-254 plates, and flash chromatography on SiO2 or florisil was used to separate and purify the crude reaction mixtures. Commercially available anhydrous AgCIO₄ was used without special precautions. CAUTION: Anhydrous AgCIO₄, especially solvated crystals containing organic compounds, can explode when struck. AgClO₄ is also hygroscopic and light sensitive, decomposes at or above 450 °C, and explodes readily at 800 °C. Several companies, including Aldrich and Strem, offer anhydrous AgClO₄; most suppliers of fine chemicals offer silver perchlorate monohydrate which can be dried by azeotropic distillation. AgAsF6 has been suggested as a safe, but ca. 10x more expensive alternative to AgCIO₄,³⁴ and all reactions reported here in this paper work equally well for either of the two silver salts. Alternatively, AgCIO₄ monohydrate can also be used but reactions proceed more slowly. For example, using catalytic AgCIO₄ monohydrate in place of commercially available "anhydrous" AgCIO₄ for the formation of 25 from 50 led to an increase in the reaction time from 10 min to 1 h, after which 90% of the desired ortho ester was isolated.

- 32. The use of racemic epoxy alcohol moiety in (2*S*)-lactate **50** gave a 1:1 mixture of diastereomeric ortho ester derivatives which were readily discernible by ¹H NMR. Only a single ortho ester isomer was detected in the rearrangement of diastereomerically pure **50**. Accordingly, the epoxy ester ortho ester rearrangement occurs with >98% stereospecificity. The stereochemistry shown for the ABO-ester **25** is based on an intramolecular S_N2-substitution at the epoxide and was confirmed by an x-ray structure analysis.
