Stereoselective Cross-Aldol Reactions of Silyl Enol Ethers with Acetals Catalyzed by Iodotrimethylsilane¹⁾

Hideki Sakurai,* Koshi Sasaki, and Akira Hosomi Department of Chemistry, Tohoku University, Sendai 980 (Received May 20, 1983)

Synopsis. Iodotrimethylsilane catalyzes effectively erythroselective aldol type condensation of silyl enol ethers with acetals.

Recently, much attention has been focused on the stereoselective aldol condensations²⁾ in relation to syntheses of acyclic β -hydroxy ketones as a structural unit of natural macrolide antibiotics.³⁾ We have found previously that iodotrimethylsilane is an efficient catalyst for the regiospecific allylation of acetals with allylsilanes.⁴⁾ As an extension of the work, we report here that highly nucleophilic silyl enol ethers (2), like allylsilanes, undergo the reaction with acetals (3) in the presence of a catalytic amount of iodotrimethylsilane (1), prepared from hexamethyldisilane and iodine at ambient temperature,⁵⁾ to afford erythro-selective β -alkoxy ketones (4) in excellent yield. (Eq. 1).

Results and Discussion

The essential feature of the reaction is rather similar to the trimethylsilyl triflate-catalyzed reaction, 6) and the results are listed in Table 1.

In all cases, the reaction of 2 with a variety of 3 proceeds very smoothly and completes within 30 min at -78 °C.⁷ It is important to note that the reaction mixture should be hydrolyzed by a saturated hydrogen sodium carbonate solution at -78 °C. One of the important features of the present reaction is the erythro selective aldol condensation. For example, reactions of benzaldehyde dimethyl acetal (3a) with silyl enol ethers, 2a and 2b, derived from cyclopentanone and cyclohexanone, gave mixtures of erythro and threo derivatives in a ratio of 99:1 and 95:5, respectively. (Eq. 2).

On the other hand, 3-trimethylsiloxy-2-pentene (**2c**, E: Z=21:79), prepared by Et_3N/Me_3SiCl in DMF,⁸⁾ gave a 57:43 mixture of erythro and threo derivatives. (Eq. 3).

a) Yields after isolation by TLC. b) Determined by NMR. Erythro and threo derivatives (4) were characterized by comparing the vicinal coupling constants (J_{ab}). Observations that J_{threo} of e.g. 4b (13 Hz) is greater than $J_{erythro}$ (4 Hz) is in accordance with other erythro-threo systems. 6,10) c) At -35 °C.

It is notable that orthoformate (6) reacts with 2 by catalysis of 1 to give β -keto acetal (7). No further reaction with the resulting β -keto acetal occurred. Apparently, the reaction of 7 with 2 is slower than the reaction of 6.

From the mechanistic point of view, it is interesting that reactions with α,β -unsaturated acetals catalyzed by 1 proceed very selectively on the acetal carbon (see Table 1). This fact suggests strongly that a silyloxonium ion A, not a carbenium ion like B, is the most important intermediate in the reaction.

Experimental

Reactions Summarized in Table 1. The following procedure is typical. To a mixture of 2 (1.2 mmol) and 3 (or 6) (1.0 mmol) in dry dichloromethane (2 ml) was added iodotrimethylsilane (0.02 g, 0.1 mmol) by a syringe under nitrogen at -78 °C. The reaction mixture was stirred for given conditions in Table 1 and hydrolyzed with a saturated solution of hydrogen sodium carbonate at -78 °C. After usual work-up, the crude product was purified by preparative thin-layer

chromatography on silica gel.9)
