Douglass F. Taber

Department of Chemistry, University of Delaware, Newark, Delaware 19716, U.S.A.

Starting from the Corey lactone (**3**), the total synthesis of a specific urinary metabolite of prostaglandin D₂, viz., (Z)-9 α ,11 β -dihydroxy-15-oxo-2,3,18,19-tetranorprost-5-ene-1,20-dioic acid (**1**) and its 5*E*-isomer is described. The synthetic material was isolated in a tricyclic form as the corresponding hemiacetal lactone (**2**). The g.c.m.s. characteristics of the methyl ester, trimethylsilyl ether derivative of this compound were identical with those previously described for the same derivative of the 11 β -tetranor metabolite of PGD₂.

Prostaglandin D₂ (PGD₂), the principal cyclo-oxygenase product of rat and human mast cells,¹ has recently become the focus of considerable interest due to its potent ability to inhibit platelet aggregation, its antitumour activity, and other unique physiological properties.² In addition, it has been shown that patients with systematic mastocytosis, a disorder characterized by increased proliferation of tissue mast cells, produce abnormally large amounts of PGD₂. It has been proposed that the released PGD₂ is an important mediator of vasodilatory episodes associated with disease.³ When PGD₂ is infused intravenously into primates it is extensively metabolised to a series of tetranor (C-16) derivatives predominantly having PGF ring structures.⁴⁻⁶ It was suggested that reduction of the 11-oxo function of PGD₂ occurred by a specific 11-keto reductase to provide an 11 β -hydroxy group. This was followed by subsequent oxidative metabolism and excretion of the corresponding tetranor metabolites. One of the most abundant urinary metabolites of PGD₂ in human subjects, was identified as⁶ 9,11-dihydroxy-15-oxo-2,3,18,19-tetranorprost-5-ene-1,20-dioic acid (**1**). It was isolated in tricyclic form (**2**) (Scheme 1) and its structure elucidated on

Scheme 1.

the basis of the mass spectrum of its methyl ester, trimethylsilyl (TMS) ether derivative. It was of interest to synthesize the 11 β -tetranor metabolite for two reasons: first, to provide unequivocal proof of structure; second, to provide sufficient material for the development of a stable isotope

dilution assay for this major urinary metabolite of PGD₂. The assay would be specific for PGD₂ by virtue of the fact that PGD₂ is the only known precursor of the 11 β -metabolite. The availability of the assay will allow the role of PGD₂ in a number of human disease states to be assessed. Direct analysis of PGD₂ *in vivo* in most clinical situations is precluded because of its metabolic instability and resulting low plasma concentrations.

The initial target for the synthesis was the 11 α -hydroxy lactone (**8**) (Scheme 2), which was obtained from the readily

(7) R = PhC₆H₄CO

(8) R = H

Scheme 2. Reagents: i, Ph₃P=CH₂CO(CH₂)₂CO₂Me, THF; ii, H₂, Pd-C; iii, HSCH₂CH₂SH, zinc triflate, CH₂Cl₂; iv, Bu^tOK, MeOH-MeCO₂Me

available Corey lactone (3) in 75% overall yield as shown. Moffatt oxidation⁷ of the Corey lactone (3) to an aldehyde (4), followed by condensation with methyl 5-(triphenylphosphoranylidene)levulinate⁸ led to the enone (5). Hydrogenation with 10% palladium on charcoal, protection⁹ of the resulting ketone (6) with ethane-1,2-dithiol, and saponification of the *p*-phenylbenzote (7) with Bu^tOK gave the required intermediate (8).

Reduction of the lactone (8) as the tetrahydropyranyl (THP) ether (9) (Scheme 3) proceeded smoothly with di-isobutylaluminium hydride (DIBAL) in tetrahydrofuran (THF) at -78°C to give the lactol (10). The use of more elevated temperatures or different aprotic solvents resulted in reduction of the terminal carboxy group to the corresponding alcohol. Three carbon homologation of the lactol (10) using traditional Wittig procedures proved to be very troublesome. The generation of phosphorane ylides in which the anion was β to an ester carboxy group led to the formation of intractable products.

It became apparent that successful homologation could only be carried out if the carboxy moiety was masked during the Wittig step as described by Corey and Shimoji.¹⁰ The ylide derived from triphenyl(2-trioxabicyclo[2.2.2]octanylethyl)-phosphonium iodide (11) prepared using dimsyl sodium¹⁰ failed to react with the lactol (10). Therefore, the homologation reaction was investigated in more detail using a number of model systems.¹¹ The use of lithium bis(trimethylsilyl)amide (LiHMDS) as the base resulted in predominant formation of *E*-isomers. The addition of hexamethylphosphoric triamide (HMPT) to the THF solvent and reduction of the temperature

to -40°C dramatically increased the amount of *Z*-isomer that was formed so that the *Z/E* ratio became 4:1.

In the light of the foregoing observations, the ylide was generated by reaction of the phosphorane (11) with LiHMDS in THF-HMPT (4:1) at 0°C . Reaction with (10) was allowed to proceed for 30 min at -40°C followed by a further 3 h at 0°C . The procedure led to an optimal yield of homologated product (50%), in which the *Z*- β,γ -unsaturated ortho ester (12) predominated over the *E*-isomer in a ratio of 4:1. The geometric isomers were separated on a silica column using hexane-acetone (9:1) containing 1% triethylamine as eluant. As was observed with model compounds¹¹ the *Z*-homologated product eluted ahead of the *E*-isomer. The ^1H n.m.r. spectrum of the pure *Z*-ortho ester differed in several distinct ways from that of the *E*-isomer. The chemical shift of the $9\beta\text{-H}$ was observed 0.1 p.p.m. to higher field and the signal from the olefinic protons was broader and more complex. In addition, the chemical shift of the methylene hydrogens α to the ortho ester was 0.25 p.p.m. downfield in the *Z*-ortho ester compared with the corresponding *E*-isomer. These characteristics were also evident in the homologated products of model lactols.¹¹

The pure *Z*-ortho ester (12) was cleaved by exposure to sodium hydrogensulphate in dimethoxyethane (DME)-water (1:1, pH 3.0) at 0°C for 20 min. The resulting ester was saponified with 0.2M lithium hydroxide at 23°C for 1 h to afford, after acidification and extractive isolation, the crude diacid. Esterification with 2.2 equiv. of tetramethylammonium hydroxide and methyl iodide in dimethylformamide (DMF) at 0°C for 20 min yielded the dimethyl ester (13).

Scheme 3. Reagents and conditions: i, DHP, *p*-TsOH, CH_2Cl_2 ; ii, DIBAL, THF, -78°C ; iii, LiHMDS, THF-HMPT; iv, DME- H_2O (1:1), NaHSO_4 , LiOH; v, Me_4NOH , MeI, CH_2Cl_2 ; vi, MeCOCl -pyridine, CH_2Cl_2 ; vii, AG50-X8 resin, MeOH; viii, MsCl, TEA, CH_2Cl_2 ; ix, CsOAc, 18-crown-6, toluene; x, LiOH, CH_2N_2

The next phase of synthesis was to invert the configuration at the 11-hydroxy group. The 9 α -hydroxy group was protected as the acetate (**14**) and the THP protecting group removed with acidic resin AG50-X8 in methanol to give the alcohol (**15**). The configuration at 11-hydroxy group was inverted by reaction of crude mesylate (**16**) with caesium acetate and 18-crown-6 ether in toluene¹² at reflux for 10 h (Scheme 3). The 11 β -acetate (**17**) was obtained in 70% yield with no evidence of any elimination products. Other reagents for inverting the 11-hydroxy function such as diethyl azodicarboxylate caused elimination reactions to predominate.

Removal of the acetyl group with potassium carbonate in methanol did not give the required dihydroxy derivative (**18**). The major product isolated showed no olefinic protons in the ¹H n.m.r. spectrum. It appeared that under basic conditions, the double bond moved into conjugation with the ester carbonyl group. This was followed by 1,4-addition to the enone by the 9 α -hydroxy group to give the cyclic ether (**19**) (Scheme 4). However, saponification with aqueous base (LiOH, 0.2M) prevented this undesirable reaction. Subsequent acidification,

extractive isolation, and esterification with diazomethane yielded the dimethyl dihydroxy diester (**18**) in 80% yield.

Oxidative deacetalization in the presence of the β,γ -unsaturated methyl ester under a variety of conditions failed to give the required product. A systematic examination of published procedures revealed that ceric ammonium nitrate¹³ (CAN) in MeCN-H₂O (4:1) smoothly converted the thioacetal (**17**) into the corresponding ketone (**20**) (Scheme 4). Saponification of the dimethyl diester (**20**) with LiOH (0.2M) for 1 h followed by acidification afforded the PGD₂ metabolite (**2**). The 11-hydroxy group and ω -side chain attached at C-12 are oriented in the same β -configuration. Presumably, this facilitates the formation of a carbocyclic hemiacetal between C-11 and C-15. Subsequent lactonization of the terminal carboxy group results in the formation of the hemiacetal lactone derivative (**2**).

The electron impact (e.i.) mass spectrum of the methyl ester TMS ether of synthetic (**2**) was identical with that reported⁶ for the tetranor urinary metabolite of PGD₂. The structure of (**2**) was confirmed by the ¹H n.m.r. spectrum of its methyl ester (**21**). It was possible to separate the two diastereoisomers of (**2**) by high resolution gas chromatography of the corresponding pentafluorobenzyl (PFB) ester, TMS ether derivative using negative ion chemical ionization mass spectrometry (n.i.c.i.m.s.). From the chromatogram it was observed that the first eluting diastereoisomer was present in slight excess over the second eluting diastereoisomer. The synthetic PGD₂ metabolite (**2**) has been used for the preparation of ¹⁸O labelled standard by treatment with 5 cycles of Li¹⁸OH. This compound will now be used for developing a g.c.m.s. assay for the urinary metabolite. The endogenous production of PGD₂ in humans and the pathophysiological role of PGD₂ in various human diseases will be assessed. Details of this work will be reported separately.

Experimental

M.p.s were measured on a Thomas Hoover capillary melting point apparatus and are uncorrected. The ¹H n.m.r. spectra were recorded in CDCl₃ on a Bruker AM 400 or an IBM NR 300 instrument. Chemical shifts (δ_H p.p.m.) are reported relative to Me₄Si as an internal standard. Routine mass spectra and accurate mass measurements were obtained on a VG 70/250 double focusing magnetic sector instrument operating in the e.i. mode. Gas chromatography/mass spectrometry (g.c.m.s.) was carried out on a Nermag R1010C quadrupole instrument interfaced to a Varian Vista gas chromatograph. Injections were made in the splitless mode on a SPB 5 fused silica capillary column (0.32 mm internal diameter, 0.25 μ m coating thickness, Supelco, Bellefonte, PA). Under standard g.c. conditions, the column was temperature programmed from 100 °C to 320 °C at 15 °C min⁻¹ with helium as carrier gas at a flow rate of 1 ml min⁻¹. Methane was used as the reagent gas for n.i.c.i.m.s. at an analyser pressure of 6.4×10^{-6} Torr.

Flash chromatography was carried out on S/P silica gel 60 Å. T.l.c. was performed on Analtech silica gel GF uniplates. Organic extracts were dried with MgSO₄. The standard work-up procedure involved dilution of the reaction mixture with saturated aqueous sodium chloride and extraction with ethyl acetate. The organic extract was washed with water and dried. After concentration under reduced pressure, the residue was purified on a silica gel column. THF was distilled from sodium benzophenone ketyl immediately prior to use. HMPT and dimethyl sulphoxide (DMSO) were vacuum distilled from calcium hydride and stored over 3 Å molecular sieves. Dry dichloromethane was obtained by distillation from P₂O₅. All other solvents were reagent grade and were used directly. Reactions were carried out under a dry nitrogen atmosphere.

*Methyl 3-[2-(2-{c-7-(Biphenyl-4-ylcarbonyloxy)-3-oxo-cis-bicyclo[3.3.0]octan-6-yl}ethyl)-1,3-dithiolan-2-yl]propionate** (7).—Dicyclohexylcarbodi-imide (1.8 g, 8.7 mmol) was added to a stirred solution of the Corey lactone (3) (1 g, 2.84 mmol) in benzene–DMSO (16.5 ml, 15:1.5). After 5 min dichloroacetic acid (180 μ l, 2.2 mmol) was added and the whole reaction mixture was stirred for 20 min, giving a thick white solution. Oxalic acid (762 mg, 2.84 mmol) in methanol (1.8 ml) was added dropwise and stirring was continued for 10 min. The reaction mixture was diluted with brine and the aqueous layer was extracted with ethyl acetate. The combined organic extracts were washed with water, dried, and concentrated to give the aldehyde (4).

The crude aldehyde (4) in THF (20 ml) was stirred with methyl 5-(triphenylphosphoranylidene)levulinate¹⁰ (1.8 g, 3.7 mmol) at room temperature for 3 h. Standard work-up and elution with 30% ethyl acetate in hexane gave the enone (5) (1.1 g, 80%), m.p. 108–110 °C (ether); δ_{H} 8.03 (2 H, d, J 8.3 Hz, ArH), 7.42–7.62 (7 H, m, ArH), 6.73 (1 H, dd, J 7.5 Hz and 15.8 Hz, olefin), 6.25 (1 H, d, J 15.8 Hz, olefin), 5.34 (1 H, m, 5-H), 5.12 (1 H, m, 3-H), 3.66 (3 H, s, CO₂Me), and 2.32–2.92 (10 H, m); m/z 462 (M^+), 233 ($M^+ - \text{PhC}_6\text{H}_4\text{CO}_2 - \text{MeOH}$), 205 ($M^+ - \text{PhC}_6\text{H}_4\text{CO}_2 - \text{MeCO}_2\text{H}$), 198, 191, 177, and 188 (Found: M^+ , 462.1744. $\text{C}_{27}\text{H}_{26}\text{O}_7$ requires M , 462.1714).

Palladium–carbon (220 mg, 10%) in ethyl acetate (10 ml) was charged with H₂ gas for 15 min. The enone (5) (1.1 g, 2.38 mmol) in ethyl acetate (10 ml) was added and the hydrogenation was continued at room temperature until the uptake of hydrogen ceased (4 h, 54 ml). The catalyst was removed by filtration, washed with ethyl acetate (10 ml), and the combined organic extracts were concentrated to give the ketone (6). This was crystallized from ether as prismatic needles (990 mg, 90%), m.p. 115–116 °C; δ_{H} 8.02 (2 H, d, J 8.3 Hz, ArH), 7.42–7.62 (7 H, m, ArH), 5.32 (1 H, m), 5.12 (1 H, m), 3.67 (3 H, s, CO₂Me), and 1.64–2.90 (14 H, m) (Found: M^+ , 464.1827. $\text{C}_{27}\text{H}_{28}\text{O}_7$ requires M , 464.1834).

The ketone (6) (900 mg, 1.94 mmol) in CH₂Cl₂ (50 ml) was stirred with ethane-1,2-dithiol (695 μ l, 8.3 mmol) and zinc triflate (1.65 g, 4.6 mmol) at room temperature for 2 h. The reaction was diluted with brine, the organic layer was separated, and the aqueous layer was extracted with CH₂Cl₂ (20 ml). The combined organic extracts were washed with water, dried, and concentrated to give a crude product. Purification on a silica gel column using ethyl acetate–hexane (1:4, v/v) afforded the pure thioacetal (7) (860 mg, 82%), m.p. 93–95 °C; δ_{H} 8.02 (2 H, d, J 8.2 Hz, ArH), 7.42–7.62 (7 H, m, ArH), 5.34 (1 H, m), 5.10 (1 H, m), 3.66 (3 H, s, CO₂Me), 3.25 (4 H, s, SCH₂CH₂S), and 1.62–2.88 (14 H, m); m/z 540 (M^+), 453 ($M^+ - \text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$), 342 ($M^+ - \text{PhC}_6\text{H}_4\text{CO}_2\text{H}$), and 191 (base peak) (Found: M^+ , 540.1645. $\text{C}_{29}\text{H}_{32}\text{O}_6\text{S}_2$ requires M , 540.1650).

*Methyl 3-[2-[2-(3-Oxo-c-7-tetrahydropyranyloxy-cis-bicyclo[3.3.0]octan-6-yl)ethyl]-1,3-dithiolan-2-yl]propionate** (9).—Bu^tOK (535 mg, 4.77 mmol) was added to a stirred solution of compound (7) (860 mg, 1.59 mmol) in methanol–methyl acetate (40 ml, 1:1) and the reaction mixture was stirred at room temperature for 2 h. Standard work-up and elution with ethyl acetate in hexane gave the pure hydroxy lactone (8) (510 mg, 88%); δ_{H} 4.98 (1 H, m, 3-H), 4.02 (1 H, m, 5-H), 3.66 (3 H, s, CO₂Me), 3.25 (4 H, s, SCH₂CH₂S), 1.48–2.88 (14 H, m) (Found: M^+ , 360.1049. $\text{C}_{16}\text{H}_{24}\text{O}_5\text{S}_2$ requires M , 360.1054).

The alcohol (8) (510 mg, 1.40 mmol) in CH₂Cl₂ (10 ml) was stirred with dihydropyran (380 μ l, 4.2 mmol) and a catalytic amount of toluene-*p*-sulphonic acid (20 mg, 0.12 mmol) at room

temperature for 1 h. Standard work-up and elution with ethyl acetate–hexane (1:4, v/v) provided the pure THP ether (9) (510 mg, 70%); δ_{H} 5.02 (1 H, m), 4.62 (1 H, m, OCH of THP), 4.14 (1 H, m), 3.88 (1 H, m), 3.68 (3 H, s, CO₂Me), 3.49 (1 H, m, OCH₂ of THP), 3.24 (4 H, s, SCH₂CH₂S), and 1.42–2.72 (20 H, m); m/z 444 (M^+), 360 ($M^+ + \text{H} - \text{THP}$), 357 ($M^+ - \text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$), 343 ($M^+ - \text{OTHP}$), and 311 ($M^+ - \text{THPOH} - \text{OMe}$) (Found: M^+ , 444.1642. $\text{C}_{21}\text{H}_{32}\text{O}_6\text{S}_2$ requires M , 444.1639).

*Methyl 3-(2-[2-[c-3-Hydroxy-c-2-(4-methoxycarbonylbut-2-enyl)-c-5-tetrahydropyranyloxy-cyclopentan-1-yl]ethyl]-dithiolan-2-yl)propionate** (13).—DIBAL (600 μ l, 0.6 mmol; 1M in THF) was added dropwise to a stirred solution of THP ether (9) (222 mg, 0.5 mmol) in THF (2 ml) at –78 °C and the mixture was stirred at that temperature for 30 min. The reaction was quenched by the addition of methanol (0.1 ml) and ethyl acetate (40 ml). After stirring at room temperature for 10 min the organic layer was separated. The aqueous layer was further extracted with more ethyl acetate (15 ml) and the combined organic extracts were washed with brine and dried. Concentration of the solvent under reduced pressure afforded the lactol (10) (202 mg, 92%) which was used directly for the next step; δ_{H} 5.64 (1 H, m), 4.92 (1 H, m), 4.62 (1 H, m, OCH of THP), 4.12 (1 H, m), 3.90 (1 H, m), 3.67 (3 H, s, CO₂Me), 3.48 (1 H, m, OCH₂ of THP), 3.24 (4 H, s, SCH₂CH₂S), and 1.52–2.64 (20 H, m) (Found: [$M^+ - \text{H}_2\text{O}$]⁺, 428.1693. $\text{C}_{21}\text{H}_{32}\text{O}_5\text{S}_2$ requires 428.1691).

Lithium bis(trimethylsilyl)amide (900 μ l, 0.9 mmol, 1.0M in THF) was added to a stirred suspension of ortho ester phosphonium iodide¹⁰ (11) (520 mg, 0.9 mmol) in THF–HMPA (2.5 ml, 4:1) at 0 °C. The reaction mixture was stirred for 30 min at the same temperature to generate the ylide. The reaction flask was cooled to –40 °C and the lactol (10) (150 mg, 0.3 mmol) in THF (2 ml) was added with stirring. Over the next 30 min the temperature was raised slowly to 0 °C. Stirring was continued for a further 2 h at 0 °C, the reaction was quenched by the addition of saturated aqueous NH₄Cl, and extraction with ethyl acetate. Concentration of the dried solvent afforded the crude 5Z-ortho ester (12) and its *E*-isomer which were separated on a silica gel column using ethyl acetate in hexane (1:9, v/v) containing 1% triethylamine. The compound that eluted first from the column was the desired 5Z-ortho ester (12) (75 mg); δ_{H} 5.51 (2 H, m, olefin), 4.63 (1 H, m, OCH of THP), 4.06 (1 H, m, 9-H), 3.96 (1 H, m, 11-H), 3.88 (7 H, s, OCH₂ of ortho ester and OCH₂ of THP), 3.68 (3 H, s, CO₂Me), 3.46 (1 H, m, OCH₂ of THP), 3.23 (4 H, s, SCH₂CH₂S), 2.92 (2 H, m, CH₂ α to ortho ester), 1.42–2.52 (20 H, m), and 0.78 (3 H, s, Me of ortho ester); m/z 586 (M^+), 502 ($M^+ + \text{H} - \text{THP}$), 501 ($M^+ - \text{THP}$), 485 ($M^+ - \text{OTHP}$), and 484 ($M^+ - \text{THPOH}$) (Found: M^+ , 586.2618. $\text{C}_{29}\text{H}_{46}\text{O}_8\text{S}_2$ requires M , 586.2634).

The later eluting compound was the 5*E*-isomer of ortho ester (12) (19 mg); δ_{H} 5.52 (2 H, sharp m, olefin), 4.65 (1 H, m, OCH of THP), 4.12 (1 H, m, 9-H), 3.96 (1 H, m, 11-H), 3.90 (7 H, s, OCH₂ of ortho ester and OCH₂ of THP), 3.68 (3 H, s, CO₂Me), 3.45 (1 H, m, OCH₂ of THP), 3.25 (4 H, s), 2.67 (2 H, m, CH₂ α to ortho ester), 1.44–2.52 (20 H, m), and 0.78 (3 H, s, Me of ortho ester) (Found: M^+ , 586.2635. $\text{C}_{29}\text{H}_{46}\text{O}_8\text{S}_2$ requires M , 586.2634).

The 5Z-ortho ester (12) (58 mg, 0.1 mmol) was dissolved in equal volumes of water (pH 3, adjusted with NaHSO₄) and DME (3 ml) and stirred at 0 °C for 20 min. Aqueous LiOH (300 μ l, 2M) was added and the solution stirred at room temperature for a further 1 h. The aqueous layer was acidified with 1M HCl to pH 4.0 and extracted three times with ethyl acetate (10 ml). The combined organic extracts were washed with brine, dried, and concentrated to afford the crude dicarboxylic acid which was

* Compounds named and numbered systematically. Prostaglandin numbering is retained in the text.

immediately stirred in DMF (2 ml) with tetramethylammonium hydroxide (100 μ l, 0.2 mmol) and methyl iodide (60 μ l, 1.2 mmol) at 0 °C for 20 min. Standard work-up and elution with acetone in ethyl acetate (1:9, v/v) gave the dimethyl 9 α -hydroxy-11 β -THP diester (**13**) (36 mg, 72%); δ_{H} 5.58 (2 H, br m, olefin), 4.58 (1 H, m, OCH or THP), 4.05 (1 H, m, 9-H), 3.92 (1 H, m, 11-H), 3.86 (1 H, m, THP), 3.68 (6 H, s, 2 \times CO₂Me), 3.48 (1 H, m, OCH₂ of THP), 3.24 (4 H, s, SCH₂CH₂S), 3.15 (2 H, m, CH₂CO₂Me), and 1.42–2.62 (20 H, m); m/z 516 (M^+), 485 ($M^+ - \text{OMe}$), 432 ($M^+ + \text{H} - \text{THP}$), 431 ($M^+ - \text{THP}$), 415 ($M^+ - \text{OTHP}$), 414 ($M^+ - \text{THPOH}$), and 396 ($M^+ - \text{THPOH} - \text{H}_2\text{O}$) (Found: M^+ , 516.2208. C₂₅H₄₀O₇S₂ requires M , 516.2202).

*Methyl 3-(2-{2-[c-3,t-5-Diacetoxy-c-2-(4-methoxycarbonyl-but-2-enyl)cyclopentan-1-yl]ethyl}dithiolan-2-yl)propionate** (**17**).—Pyridine (25 μ l, 0.3 mmol) and acetyl chloride (15 μ l, 0.15 mmol) were added to a solution of the alcohol (**13**) (26 mg, 0.05 mmol) in CH₂Cl₂ (1 ml) at 0 °C and the reaction mixture was stirred for 30 min. Standard work-up and elution with acetone in hexane (1:9, v/v) afforded the dimethyl 9 α -acetoxy-11 α -THP diester (**14**) as an oil (22 mg, 80%); δ_{H} 5.56 (2 H, m, olefin), 5.01 (1 H, m, 9-H), 4.58 (1 H, m, OCH of THP), 3.86 (2 H, m, 11-H and THP), 3.68 (6 H, s, 2 \times CO₂Me), 3.46 (1 H, s, THP), 3.24 (4 H, s, SCH₂CH₂S), 3.06 (2 H, m, CH₂CO₂Me), 2.04 (3 H, s, OCOMe), and 1.42–2.60 (20 H, m); m/z 527 ($M^+ - \text{OMe}$), 474 ($M^+ + \text{H} - \text{THP}$), 413 ($M^+ - \text{THP} - \text{MeCO}_2\text{H}$), 397 ($M^+ - \text{OTHP} - \text{MeCO}_2\text{H}$), and 396 ($M^+ - \text{THPOH} - \text{MeCO}_2\text{H}$) (Found: [$M - \text{OMe}$]⁺, 527.2127. C₂₆H₃₉O₇S₂ requires M , 527.2137).

The THP ether (**14**) (20 mg) in methanol (2 ml) was stirred with cation exchange resin AG50-X8 (100 mg; H⁺ form, Bio-Rad Laboratories, Richmond, CA) at 23 °C for 6 h. The resin was removed by filtration and washed with methanol (5 ml). Concentration of the methanol solution and purification on a silica gel column using acetone in hexane (1:4, v/v) afforded the pure dimethyl 9 α -acetoxy-11 α -hydroxy diester (**15**) (15 mg, 88%); δ_{H} 5.54 (2 H, m, olefin), 5.08 (1 H, m, 9-H), 3.92 (1 H, m, 11-H), 3.68 (6 H, s, 2 \times CO₂Me), 3.24 (4 H, s, SCH₂CH₂S), 3.08 (2 H, s, CH₂CO₂Me), 2.04 (3 H, s, OCOMe), and 1.48–2.60 (14 H, m); m/z 474 (M^+), 456 ($M^+ - \text{H}_2\text{O}$), 443 ($M^+ - \text{OCH}_3$), 396 ($M^+ - \text{MeCO}_2\text{H} - \text{H}_2\text{O}$), 381, 327, 303, and 191 (Found: M^+ , 474.1758. C₂₂H₃₄O₇S₂ requires M , 474.1770).

Triethylamine (18 μ l, 0.15 mmol) and methanesulphonyl chloride (12 μ l, 0.15 mmol) were added to a stirred solution of the alcohol (**15**) (12 mg, 0.025 mmol) in CH₂Cl₂ (1 ml) at –20 °C and the reaction mixture was stirred for 30 min at that temperature. The reaction mixture was diluted with saturated brine (5 ml) and extracted with CH₂Cl₂ (3 \times 5 ml). The organic extract was washed with water, dried, and evaporated to give the crude mesylate (**16**) which was used without further purification.

The crude mesylate (**16**) in toluene (2 ml) was heated under reflux with 18-crown-6 ether (6 mg, 0.02 mmol) and caesium acetate (15 mg, 0.08 mmol) at 115 °C for 8 h. Toluene was removed under reduced pressure and the residue dissolved in ethyl acetate. The ethyl acetate was washed sequentially with water and brine then dried and concentrated. Purification on a silica gel column by elution with acetone in hexane (1:9, v/v) yielded dimethyl 9 α ,11 β -diacetoxy diester (**17**) (8 mg, 65%); δ_{H} 5.56 (2 H, m, olefin), 5.28 (1 H, m, 11-H), 5.18 (1 H, m, 9-H), 3.64 (6 H, s, 2 \times CO₂Me), 3.22 (4 H, s, SCH₂CH₂S), 3.08 (2 H, s, CH₂CO₂Me), 2.08 (3 H, s, OCOMe), 1.98 (3 H, s, OCOMe), and 1.48–2.58 (14 H, m); m/z 516 (M^+), 485 ($M^+ - \text{OMe}$), 484 ($M^+ - \text{MeOH}$), 457 ($M^+ - \text{OCOMe}$), 456 ($M^+ -$

MeCO₂H), 429 ($M^+ - \text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$), and 396 ($M^+ - 2 \times \text{MeCO}_2\text{H}$) (Found: M^+ , 516.1853. C₂₄H₃₆O₈S₂ requires M , 516.1852).

Base-catalysed Cyclization of Compound (17).—Anhydrous powdered K₂CO₃ (2.7 mg, 0.02 mmol) was added to a stirred solution of the dimethyl diester (**17**) (10.3 mg, 0.02 mmol) in anhydrous methanol (1 ml) and the mixture was stirred at room temperature for 2 h. The reaction mixture was neutralized with 1M HCl and stirred for a further 10 min in an ice bath. After dilution with ethyl acetate (5 ml) the resulting solution was washed with aqueous NaHCO₃ followed by brine. The organic layer was dried and evaporated and the residue chromatographed on a silica gel column using acetone–hexane (1:4, v/v) to give the 9-deoxy-5,9 α -epoxy derivative (**19**) (6.5 mg, 75%) as a mixture of enantiomers; δ_{H} 4.28 (1 H, m), 4.18 (2 H, m), 3.68 (3 H, s, CO₂Me), 3.66 (3 H, s, CO₂Me), 3.22 (4 H, s, SCH₂CH₂S), and 1.60–2.81 (18 H, m); m/z 432 (M^+), 401 ($M^+ - \text{OMe}$), 345 ($M^+ - \text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$), and 327 ($M - \text{CH}_2\text{CH}_2\text{CO}_2\text{Me} - \text{H}_2\text{O}$) (Found: M^+ , 432.1628. C₂₀H₃₂O₆S₂ requires M , 432.1640).

(Z)-9 α -11 β -Dihydroxy-15-oxo-2,3,18,19-tetranorprost-5-ene-1,20-dioic Acid (1).—Ceric ammonium nitrate (45 mg, 0.08 mmol) was added to a stirred solution of the thioacetal (**17**) (10.2 mg, 0.02 mmol) in MeCN–H₂O (1.2 ml, 4:1) and the mixture was stirred at room temperature for 1 h. Standard work-up and elution with acetone–hexane (1:4, v/v) gave the pure 9 α ,11 β -diacetoxy ketone (**20**) (6 mg, 70%); δ_{H} 5.56 (2 H, m), 5.24 (1 H, m, 11-H), 5.18 (1 H, m, 9-H), 3.64 (6 H, s, 2 \times CO₂Me), 3.08 (2 H, m, CH₂CO₂Me), 2.04 (3 H, s, OCOMe), 1.98 (3 H, s, OCOMe), 1.80–2.64 (14 H, m); m/z 380 ($M^+ - \text{MeCO}_2\text{H}$), 320 ($M^+ - 2 \times \text{MeCO}_2\text{H}$), 311 ($M^+ - \text{CH}_2\text{COCH}_2\text{CH}_2 - \text{CO}_2\text{Me}$), 289 ($M^+ - 2 \times \text{MeCO}_2\text{H} - \text{OMe}$), and 288 ($M^+ - 2 \times \text{MeCO}_2\text{H} - \text{MeOH}$) (Found: [$M - \text{MeCO}_2\text{H}$]⁺, 380.1835. C₂₀H₂₈O₇ requires 380.1835).

The 9 α ,11 β -diacetoxy ketone (**20**) (10 mg, 0.02 mmol) was dissolved in a mixture of DME–H₂O (2 ml, 1:1) and aqueous LiOH (0.2 ml, 2M). The mixture was stirred at room temperature for 1 h. Acidification with 1M HCl (final pH 3.0) was followed by extraction into ethyl acetate (3 \times 5 ml). The organic layer was dried and concentrated to give the γ -lactone (**2**). This was then methylated by adding ethereal diazomethane. Purification on a small column using acetone–hexane (1:9, v/v) gave the methyl ester (**21**) (5 mg); δ_{H} 5.56 (2 H, m, olefin), 4.32 (2 H, m, 9- and 11-H), 3.66 (3 H, s, CO₂Me), and 1.52–3.22 (16 H, m); m/z 324 (M^+), 396 ($M^+ - \text{H}_2\text{O}$), 293 ($M^+ - \text{OMe}$), 292 ($M^+ - \text{MeOH}$), and 280 ($M^+ - \text{CO}_2$) (Found: M^+ , 324.1574. C₁₇H₂₄O₆ requires M , 324.1572). The methyl ester (**21**) could be readily converted back into the free acid (**2**) using LiOH as described above.

The methyl ester (**21**) was converted into the TMS ether (bistrimethylsilyltrifluoroacetamide) and analysed by g.c.m.s. Chromatography was carried out on a 10 m SPB 5 fused silica column using the standard conditions. The derivative eluted as a single peak with a retention time of 8.20 min. The e.i. mass spectrum of the derivative was identical with that reported previously: m/z 396 (M^+), 381 ($M^+ - \text{Me}$), 337 ($M^+ - \text{CO}_2\text{Me}$), 306 ($M^+ - \text{Me}_3\text{SiOH}$), 295 and 274 ($M^+ - \text{Me}_3\text{SiOH} - \text{MeOH}$). γ -Lactone acid (**2**) was converted into the PFB ester, TMS ether derivative using published procedures¹⁴ and analysed by capillary column g.c.n.i.c.i.m.s. Under these conditions one major ion corresponding to the expected¹⁵ [$M - \text{PFB}$] anion was observed. High resolution capillary column chromatography on a 30 m SPB5 column using the standard conditions resolved the two diastereoisomers of (**2**). The first eluting component had a retention time of 14.30 min

* As on page 2824.

and the second 14.45 min. From the reconstructed gas chromatogram it was estimated that diastereoisomers were present in a ratio of 55:45 respectively.

Supplementary Material.—The *E*-isomers of all the reported compounds were prepared under identical reaction conditions to the corresponding *Z*-isomers. Details of their ¹H n.m.r. and mass and spectra are available as a supplementary publication. [SUP. NO. 56720 (2 pages)].*

Acknowledgements

We thank Dr. Tom Harris and Dr. Jin Cha for helpful discussions and Dr. Brian Sweetman for the accurate mass determinations. This work was supported by National Institutes of Health and the United States Public Health Services.
