Summary. Phenylbromodiazirine (1) reacts with a variety of primary and secondary amines affording a series of aminophenylcarbenes (3).

Aminocarbenes are of interest because the strongly electron-donating amino group should significantly affect their stability and philicity.¹ Several generative methods have been reported for aminocarbenes, including the thermal reversion of formal aminocarbene dimers.² thermal elimination of an amine or alcohol from an amide acetal or related triheteroatomic substituted methane, 3 deprotonation of amino-stabilized carbocations, 3b,4 and the action of carbon atoms on ammonia or amines.⁵ However, excepting a single report of the generation of aminocyanocarbene by pyrolysis or photolysis of a tosylhydrazone salt,⁶ aminocarbenes have not been produced from the classic diazoalkane⁷ or diazirine⁸ carbene precursors. Now we describe reactions of amines with phenylbromodiazirine⁹ that appear to occur by initial exchanges¹⁰ affording aminophenyldiazirines, followed by nitrogen loss and the liberation of aminophenylcarbenes.

Reactions of phenylbromodiazirine (1) and amines were carried out at 25° C by stirring 1 - 2 mmol of 1 with a 4 ~ 5 molar excess of amine for 2 (1° amines) or 16 (2° amines) hrs., either in a sealed Carius tube or in a dessicant-protected flask, depending on the volatility of the amine. Reaction products were separated by quenching with 10 ml of aq. 1 M NaOH, followed by extraction with 3 x 10 ml of pentane. Standard manipulations, followed by Kugelrohr distillation and, where appropriate, crystallization, afforded pure products. Table I summarizes the results of six reactions of 1 with various 1° and 2° amines. No reactions were observed between 1 and ammonia or trimethylamine.

Products were identified by comparisons of physical properties, gc retention times, and nmr spectra with those of authentic samples prepared by condensations of the amines with benzaldehyde. References to the authentic compounds appear in the Table.

The most reasonable mechanism to account for the reactions of Table I posits an initial amine/bromide exchange¹⁰ of 1, affording an unstable aminophenyldiazirine, 2, that yields aminophenylcarbene 3 upon loss of nitrogen, eq. (1). In Cases 1 and 2 of Table I, where R' = H, 3 affords an imine, probably by 1,2 N+C H migration. In contrast, when R = R' = alkyl (Cases 3 and 4), **3** attacks a second amine molecule, providing a (formal) N-H insertion product.

Variations on this theme are illustrated by Cases 5 and 6, where the aminocarbenes are trapped by intramolecular cyclizations involving OH or NH functionalities; <u>e.g.</u> for Case 5:

Parallels to these reactions of **3** appear in the work of Shevlin.⁵ HCNHMe, from atomic carbon and methylamine, gives $CH_2=NMe^5$ (compare Case 1), whereas $HCNMe_2$ from atomic carbon and dimethylamine mainly affords the intermolecular product $H_2C(NMe_2)_2^{11}$ (compare Case 3).

Two further points invite comment. The initial exchange reaction [eq. (1)] probably occurs via an intimate phenyldiazirinium-bromide ion pair.^{10,12} Not surprisingly, phenyl<u>fluorodiazirine</u> and Me₂NH do not react thermally at 25°C over 24 hrs; the poor fluoride leaving group inhibits amine/halide exchange. However, <u>photolysis</u> (3 hrs) of the reaction mixture affords 87% of the <u>bis</u>-dimethylamino product (Table I, Case 3), probably by the sequence of eq. (3). Although

intermediates other than 4 could be written, the net halocarbene \rightarrow aminocarbene transformation is analogous to the older halocarbene \rightarrow alkoxycarbene interconversion.¹³

Finally, the philicities of our aminophenylcarbenes are uncertain. The bisaminocarbenes $(\underline{m} \sim 3.6)^{14}$ and alkoxyaminocarbenes $(\underline{m} \sim 2.9)^{14}$ manifest the anticipated¹ nucleophilicity in their intermolecular chemistry.²⁻⁴ The aminophenylcarbenes of Table I $(\underline{m} \sim 2.0)^{14}$ and the parent HCNMe₂ itself⁵ $(\underline{m}=1.65)$,¹⁴ however, display intramolecular and intermolecular chemistries that are seemingly characterized by the 1,2 H-shifts and NH or OH "insertions" familiar from reactions of the more common electrophilic carbenes.¹⁵ It remains to probe the electronic character of the aminophenylcarbene reactions.¹⁶ Additionally, the simple halodiazirine/amine exchange reactions described here should give access to a variety of new aminocarbenes. These will be the subject of future reports.
