<sup>b</sup> Department of Chemistry, Odense University, DK-5230 Odense M, Denmark

Alkyl 3-alkoxy-4-bromocarboxylates are prepared by the Lewis acid-catalyzed reaction of  $\alpha$ -bromoaldehyde acetals with ketene. Base-catalyzed cyclization of these intermediates affords 2-alkoxycyclopropanecarboxylic esters.

Cyclopropanecarboxylic esters and acids constitute important parts of natural compounds as well as of industrial products, e.g. pesticides.<sup>3</sup> General and convenient procedures for the synthesis of these intermediates<sup>4</sup> are therefore essential. The most common route to this class of compounds consists of adding carbene synthons, e.g., diazo compounds, to olefins. The yields of this procedure vary; the efficiency of the method has therefore been improved by the addition of transition-metal catalysts.<sup>5-7</sup> However, the procedure suffers from the dangerous character of diazo compounds.

Alkyl 2-alkoxycyclopropanecarboxylates can be prepared by the following methods:

- addition of alkyl diazoacetates to vinyl ethers;<sup>8</sup>
- reaction of alkyl 4-bromo-2-butenates with sodium alkoxides and subsequent cyclization;<sup>8</sup>
- addition of alcohols to alkyl 4-chloro-2-butenates followed by potassium hydroxide-mediated cyclization<sup>9</sup> (hydrolysis of the intermediate alkyl 4-chloro-2-alkoxybutanoate has also been reported to give the 3-alkoxy- $\gamma$ -lactone<sup>10</sup>);
- simultaneous addition of bromine and an alcohol to alkyl 3-butenates followed by sodium alkoxide-mediated cyclization.<sup>8</sup>

Procedure (a) has the disadvantage of an expensive starting material and of low yields even when in the reaction the alkoxide is added portionwise over several hours. Procedure (c) suffers from low yield, which is partially due to hydrolysis of the product. A low yield is also obtained in procedure (d) which has the additional disadvantage that a mixture of isomers is formed in the addition reaction, the Br-atom occurring in both the 3- and 4-positions in the products.

The procedure described here represents a general alternative route to the intermediate 3-alkoxy-4-halobutanoates **3** starting from alkanals **1**. These aldehydes are brominated and acetalized in a one-pot reaction by addition of bromine in methanol<sup>10</sup> to give the 2-bromoalkanal acetals **2** (X = Br) which in the presence of a Lewis acid react with ketene (which is known to undergo insertion reactions with compounds having activated C=O bonds<sup>11</sup>) to give 3-alkoxy-4-bromobutanoic esters **3**. Since the sodium ethoxide-mediated cyclization procedure<sup>9</sup> was found to be unsatisfactory for the model case **3a** we elaborated an alternative method for the cyclization **3**  $\rightarrow$  **4** using solid potassium hydroxide in dimethylformamide. The resultant 2-methoxycyclopropanecarboxylic esters **4** can be easily hydrolyzed to the free carboxylic acids **5**.

In the case of **2a**, the ketene insertion is catalyzed by an acidic montmorillonite (KSF/0) to give the ester **3a** in 70% yield.

As regards the stereochemistry of compounds **4**, the <sup>1</sup>H-NMR data (Table 5) suggest that mainly the thermodynamically stable *trans* compounds are formed. Only in the case of **4d** are both *cis*- and *trans* isomers observed. This may be due to the steric

restrictions imposed upon the system by the phenyl ring at C-3 of the cyclopropane ring. Second-order effects in the spectra prevent stereochemical assignment of the isomers of compounds

<sup>a</sup> Chloroacetaldehyde dimethyl acetal (**2a**) was purchased.

<sup>b</sup> Microanalyses of **2b** and **2g**: C  $\pm$  0.35, H  $\pm$  0.24.

<sup>c</sup> Reported in Lit.<sup>14</sup> without physical data.

<sup>d</sup> Reported in Lit.<sup>19</sup> without physical data.

<sup>e</sup> The oxidation product methyl 3-phenylpropanoate is formed in approximately the same amount.

**4a** and **4e**, whereas for **4b** only one of the possible stereoisomers (*trans*) can be identified. From the  $^1\text{H}$ -NMR spectra of compounds **5** (Table 5) it is evident that no isomerization occurs during hydrolysis.

Microanalyses were performed by NOVO Microanalytical Laboratory, Bagsvaerd, and by the Microanalytical Laboratory at the University of Copenhagen. Mass spectra were recorded at the MS-laboratory at Odense University using a Varian MAT 311A-spectrometer and chemical ionization with isobutene as ionization gas.  $^1\text{H}$ - and  $^{13}\text{C}$ -NMR spectra were recorded on a Bruker AC 250 spectrometer.

A ketene gas flow ( $\approx 0.6$  mol/h) was obtained by pyrolysis of acetic anhydride.<sup>12,13</sup> Other reagents and solvents were used in commercially available qualities. Silica gel (230–400 mesh, Merck) was used for chromatography. The clay KSF/0 used in the conversion **2a**  $\rightarrow$  **3a** is an acid-treated montmorillonite from Süd-Chemie, D-8000 München.

#### 2-Bromoalkanal Dimethyl Acetals **2b–g**; General Procedure:

Molecular sieves (3 Å; 25 g) are added to a solution of the mechanically stirred aldehyde **1b–g** (1.0 mol) in MeOH (500 mL). The mixture is heated to reflux, and  $\text{Br}_2$  (159.8 g, 1.0 mol) is added dropwise. When the

addition is complete, the mixture is refluxed until disappearance of the starting material (as detected by GC). After cooling to room temperature, the mixture is stirred with  $\text{K}_2\text{CO}_3$  (70 g, 0.5 mol) for 1 h, and filtered. Saturated aqueous NaCl (500 mL) is added and the product is extracted with pentane (200 mL). The extract is concentrated under reduced pressure and the product is distilled.

#### Methyl 4-Halo-3-methoxyalkanoates **3a–g**; General Procedure:

The acetal **2a–g** (0.2 mol) is cooled to  $\approx 5^\circ\text{C}$ ,  $\text{Et}_2\text{O} \cdot \text{BF}_3$  (1 mL) is added, and ketene gas ( $\approx 0.3$  mol) is bubbled through the mixture. After disappearance of the starting material (as detected by GC), the solution is poured into a stirred mixture of hexane (100 mL) and 25% aqueous  $\text{NH}_3$  (75 mL). The phases are separated, the aqueous phase is washed with hexane ( $2 \times 25$  mL), the combined organic phases are dried ( $\text{Na}_2\text{SO}_4$ ), and concentrated under reduced pressure, and the residue is distilled to give the pure product **3**.

#### Methyl 4-Chloro-3-methoxybutanoate (**3a**):

A solution of chloroacetaldehyde dimethyl acetal (**2a**; 31.15 g, 0.25 mol) in  $\text{CH}_2\text{Cl}_2$  (100 mL) is cooled to  $0^\circ\text{C}$  and KSF/0 (2.0 g) is added. Ketene gas ( $\approx 0.3$  mol) is bubbled through the mixture. When the starting material has been completely consumed (GC) the mixture is filtered immediately and the filtrate is concentrated under reduced pressure. The residue is distilled to give the pure product **3a**; yield: 29.1 g (70%); bp  $80–82^\circ\text{C}/10$  Torr.

#### Methyl 2-Methoxycyclopropanecarboxylates **4a–g**; General Procedure:

A stirred dispersion of KOH (powdered; 5.6 g, 0.1 mol) in DMF (50 mL) is cooled to  $0^\circ\text{C}$ . The methyl 4-halo-3-methoxyalkanoate **3a–g** (0.1 mol) is added dropwise, and the mixture is stirred for 2 h. Then, powdered KOH (0.56 g, 0.01 mol) is added every 1 hour (altogether 3–5 times) with continued stirring at  $0^\circ\text{C}$  for the time given in Table 3. The slow portionwise addition of base avoids the formation of a mixture of ester and free acid. The mixture is then acidified by the addition to 1 M aq. HCl (600 mL) and extracted with  $\text{Et}_2\text{O}$  ( $3 \times 150$  mL). The extract is dried ( $\text{Na}_2\text{SO}_4$ ) and concentrated under reduced pressure. In most cases, the product thus obtained is analytically pure. Otherwise, further purification may be achieved by distillation or column chromatography using EtOAc/petroleum ether (1:9) as eluent.

#### 3-Alkyl-2-methoxycyclopropanecarboxylic Acids **5a–g**; General Procedure:

The methyl 3-alkyl-2-methoxycyclopropanecarboxylate **4a–g** (0.015 mol) is stirred with 4 M aq. NaOH (10 mL) for 4–5 h. The mixture is then neutralized with 4 M aq. HCl and extracted with petroleum ether ( $3 \times 10$  mL). The extract is dried ( $\text{Na}_2\text{SO}_4$ ) and concentrated under reduced pressure to give the analytically pure compound **5a–g**.

<sup>a</sup> Mixture of diastereoisomers.

The diastereoisomers of compound **5d** can be separated by column chromatography [100×4 cm; silica gel; 800 mL; benzene/dioxane/AcOH (80:19:1)]. The isomers are identified by <sup>1</sup>H-NMR spectroscopy.

(1*S*,2*S*,3*R*)-2-Methoxy-3-phenylcyclopropanecarboxylic Acid; mp 96–97°C.

(1*S*,2*S*,3*S*)-2-Methoxy-3-phenylcyclopropanecarboxylic Acid; mp 109–110°C.

The authors thank Drs. J. Møller and G. Bojesen for recording the mass spectra and Dr. T. Bjørholm for the NMR work.
