The reaction between Si₂Ph₄O(OLi)₂ (**1**) and TiCl₄ in 2:1 or 3:1 molar ratio gave on addition of pyridine (py) the titanatrisiloxane compound [Ti{OSiPh₂(OSiPh₂)₂O}(py)₂]₂·2C₆H₅Me (**2**). Treatment of ZrCl₄ with (**1**) in 1:2 molar ratio gave the zirconadisiloxane system Li₂Zr(OSiPh₂OSiPh₂O)₃·3py·1.5C₆H₅Me (**3**). Compound (**2**) was also isolated from reactions employing the diol Si₂Ph₄O(OH)₂ and TiCl₄ in 2:1 molar ratio in the presence of pyridine. Siloxane chain expansion was also observed in the product from reaction of (**1**) with SiMe₂Cl₂ but not from reaction with SiMe₃Cl. The formation of the cyclic titanatrisiloxane and the cyclic tetrasiloxane is presumably a consequence of the ring strain in the titanadisiloxane and trisiloxane systems respectively, rather than a tendency of the siloxanediolate species (**1**) to oligomerise in the presence of base or metal halides. Compounds (**2**) and (**3**) have been studied by X-ray crystallography.

Cyclic siloxane systems, important intermediates in the production of silicones, have been thoroughly investigated,¹ but little is known of related cyclic metallasiloxanes. We have recently reported² on the isolation of the compound *cis*-[Ti{OSiPh₂(OSiPh₂)₂O}(py)₂]₂ (**2**) (py = pyridine) from the reaction between TiCl₄ and Si₂Ph₄O(OLi)₂ (**1**). We have now carried out the reaction between compound (**1**) and ZrCl₄ under conditions similar to those used for the titanium reaction. The product was shown by crystallography to be the essentially octahedral zirconadisiloxane tris chelate system, Li₂[Zr(OSiPh₂OSiPh₂O)₃]₂·3py (**3**). Chain expansion of the siloxane as found in the reaction with TiCl₄ was not observed in the case of zirconium. The chemistry described in this paper is summarised in the Scheme.

Results and Discussion

Compounds (**2**)–(**5**), Table 1, represent the few reported examples of well characterised cyclic metallasiloxanes of the Group 4 transition metals. The mode of formation of the oligomeric metallasiloxanes (**4**)³ and (**5**)⁴ was not clear but must involve condensation of the precursor silanediol. Compounds (**2**) and (**3**) were prepared by treatment of the metal halides in tetrahydrofuran (thf) at 0 °C with Si₂Ph₄O(OLi)₂ in thf in 1:2 or 1:3 and 1:2 molar ratios respectively. When pyridine was added to concentrated toluene solutions of the products and these mixtures heated until clear solutions were obtained and allowed to cool slowly, colourless cubic, apparently air-stable crystals of (**2**) and (**3**) were obtained. The apparently low 'melting point' of the titanium compound was probably due to the release of co-ordinated pyridine. Similar features were observed in the i.r. spectra of the two species, the main differences being that bands, tentatively assigned to Si–O–Si

Table 1. Cyclic metallasiloxanes of Ti, Zr, and Hf

Compound	Reagents (relative molar quantities)	Ref.
(2) <i>cis</i> -[Ti{OSiPh ₂ (OSiPh ₂) ₂ O}(py) ₂] ₂	TiCl ₄ , Si ₂ Ph ₄ O(OLi) ₂ , py (1:2 or 3, excess)	<i>a</i>
(3) Li ₂ [Zr(OSiPh ₂ OSiPh ₂ O) ₃] ₂ ·3py	ZrCl ₄ , Si ₂ Ph ₄ O(OLi) ₂ , py (1:2, excess)	<i>a</i>
(4) [NEt ₂ H] ₂ [M(OSiPh ₂ OSiPh ₂ O) ₃] ₂ M = Zr or Hf	M(NEt ₂) ₄ , SiPh ₂ (OH) ₂ (1:6)	3
(5) [Ti(OSiPh ₂ (OSiPh ₂) ₃ O) ₂] ₂	Ti(OPr ⁱ) ₄ , SiPh ₂ (OH) ₂ (1:8)	4

stretching, in the region 1 120–1 010 cm⁻¹ (see Experimental section for data), were less defined and at slightly higher wavenumbers for the titanium compound. The two different chemical environments of silicon in compound (**2**) were distinguished by ²⁹Si n.m.r. spectroscopy with the resonance due to the silicon distal to titanium occurring at slightly higher field. The ²⁹Si n.m.r. spectrum for compound (**3**) consisted of a single resonance, probably indicating rapid exchange of the bridging lithiums. This was supported by the observation of a single resonance in the ⁷Li n.m.r. spectrum of (**3**). The pyridine-promoted dehydrochlorination reaction as shown in equation (1) was reported to give compound (**6**) in 14% yield.⁵ We have

found that when this material[‡] isolated as described⁵ was treated with toluene–pyridine mixtures, compound (**2**) and not the pyridine adduct of (**6**) was obtained. Furthermore examination of the remaining crude products from reaction (1) revealed the presence of the titanatrisiloxane (**2**). The apparently facile

formation of cyclic titanatrissiloxanes from these reactions is probably promoted by ring strain in the cyclic titanadisiloxane system. The precursor silanolate did not undergo chain expansion in reactions with chlorotrimethylsilane. The mass spectrum of the product was consistent with the formation of the hexamethyltetraphenyltetrasiloxane compound as shown in the Scheme.

However with dichlorodimethylsilane chain expansion did occur and the cyclic tetrasiloxane $\text{Si}_4\text{Me}_2\text{Ph}_6\text{O}_4$ was isolated. These experiments suggested that siloxane chain expansion occurred in order to relieve ring strain energy and not because the precursor disiloxanediolate was intrinsically unstable in the presence of base or metal halide compounds. The formation of the zirconadisiloxane compound (3) gave further weight to this suggestion.

Crystallography.—The structures of compounds (2) and (3) are depicted in Figures 1 and 2. Selected bond lengths and angles are given in Tables 2 and 3 with fractional atomic co-ordinates in Tables 4 and 5. The titanium atom in compound (2) has distorted *cis*-octahedral geometry. The eight-membered titanatrissiloxane rings were found to be almost

planar and the Si–O(Si) bond lengths and Si–O–Si angles were close to those previously reported for the tetrahedral compound $[\text{Ti}\{\text{OSiPh}_2(\text{OSiPh}_2)_3\text{O}\}_2]$ (5). A narrowing of the O–Ti–O angles towards octahedral values [95.5(2) and 102.6(3)°] was accompanied by slight lengthening of the Ti–O bonds [1.874(5)–1.836(5) Å] compared to those in (5) [1.777(5)–1.791(5) Å], where some degree of π interaction is likely. The zirconium complex (3) showed an octahedral arrangement of the three chelating disiloxanediolate groups, similar to that previously found for the dianion (4). A novel feature of the present molecule concerns the internal solvation of the lithium cations with both face- and edge-bridging observed. All six Zr–O distances were slightly different and in the range 2.015(7)–2.131(6) Å, the shortest Zr–O distance being associated with the only oxygen atom not also co-ordinated to lithium. The shortest Zr–O distance in compound (4) was 2.070(4) Å. Chelate angles, O–Zr–O, were in the range 85.3(3)–88.1(3)° close to those previously reported. The angles described by the *cis*-O–Zr–O atoms [77.8(3)–109.6(3)°] and the *trans*-O–Zr–O atoms [160.8(2)–168.4(2)°] showed more distortion from regular octahedral values than found in the case of compound (3), probably because of the internally solvated lithium atoms.

Experimental

All reactions were carried out in an atmosphere of purified nitrogen. Melting points were recorded on samples sealed in capillaries under nitrogen. Spectrometers: i.r., Perkin-Elmer 577 (spectra in Nujol mulls); n.m.r., Bruker (400 MHz) in $[\text{}^2\text{H}_8]\text{toluene}$ at 310 K (data relative to LiNO_3 in D_2O or SiMe_4 in $[\text{}^2\text{H}_8]\text{toluene}$); mass, Kratos MS 902 (at 70 eV 1.12×10^{-17} J).

cis- $[\text{Ti}\{\text{OSiPh}_2(\text{OSiPh}_2)_2\text{O}\}_2(\text{py})_2] \cdot 2\text{C}_6\text{H}_5\text{Me}$ (2).—To a solution of TiCl_4 (0.276 g, 1.5 mmol) in benzene (40 cm^3) at 0 °C was added a solution of dilithium tetraphenyldisiloxanediolate (1) (4.5 mmol) in tetrahydrofuran. The resulting colourless solution was stirred overnight and the thf was then evaporated. The crispy solid residue was stirred in toluene (40 cm^3) and the filtered toluene solution then concentrated to approximately 15 cm^3 . Pyridine was added until the solution became turbid and the mixture was then heated until a clear solution was obtained. On slow cooling colourless cubic crystals of compound (2) were deposited. Yield 1.26 g (52%), m.p. 97–100 °C. I.r.: 1 600m, 1 590w, 1 430s, 1 115vs, 1 050vs, 1 025s, 920vs, 740m, 715s, 695s, and 525s cm^{-1} .

$\text{Li}_2[\text{Zr}(\text{OSiPh}_2\text{OSiPh}_2\text{O})_3]\cdot 3\text{py}\cdot 1.5\text{C}_6\text{H}_5\text{Me}$ (3).—This compound was prepared in the manner described above from ZrCl_4 (1.26 g, 5.4 mmol) in thf (40 cm^3) and a solution of (1) (1.62 mmol) in thf (40 cm^3). Yield 5.86 g (65%), m.p. 232 °C (Found: C, 67.9; H, 5.0; N, 2.7. Calc. for $\text{C}_{97.5}\text{H}_{87}\text{Li}_2\text{N}_3\text{O}_9\text{Si}_6\text{Zr}$: C, 68.2; H, 5.1; N, 2.5%). I.r.: 1 595w, 1 590w, 1 425s, 1 120s, 1 110s, 1 030m, 1 010s, 990s, 940s, 740s, 715m, 700m, and 530s cm^{-1} . N.m.r. at 310 K: ^{29}Si , −40.27(s); ^7Li , 1.06(s) p.p.m.

2,2-Dimethyl-4,4,6,6,8,8-hexaphenylcyclotetrasiloxane from SiMe_2Cl_2 and $\text{Si}_2\text{Ph}_4\text{O}(\text{OLi})_2$.—To a solution of compound (1) (2.4 mmol) in thf (20 cm^3) at 0 °C was added dropwise a solution of SiMe_2Cl_2 (0.31 g, 2.4 mmol) in thf (15 cm^3). The reaction mixture was stirred for several hours and then the thf was evaporated. The solid residue was treated with pentane and filtered. A white solid crystallised from the concentrated pentane solution. Yield: 1.62 g, 64% based on SiMe_2Cl_2 (Found: C, 68.2; H, 5.5. Calc. for $\text{C}_{38}\text{H}_{36}\text{O}_4\text{Si}_4$: C, 68.2; H, 5.5%). ^1H N.m.r. (CD_2Cl_2): 0.1 (s, 6 H, Me_2Si), 7.18—7.3 (m, 12 H), 7.32—7.42 (m, 6 H), and 7.46—7.6 (m, 12 H) m/z 668(2) $[M]^+$ and 591(100%) $[M - \text{Ph}]^+$.

1,1,1,7,7,7-Hexamethyl-3,3,5,5-tetraphenyltetrasiloxane.—To a solution of compound (1) (2.4 mmol) in thf (20 cm^3) at 0 °C was added dropwise SiMe_3Cl (0.52 g, 4.82 mmol) in thf (15 cm^3). The reaction mixture was stirred at room temperature for 6 h and the thf was evaporated. The residue was treated with pentane and the filtered pentane extract dried giving a low-melting white solid. Yield: 1.18 g, 87%. ^1H N.m.r. (CD_2Cl_2): 0.0(s), 7.2—7.43(m), and 7.53—7.64(m).

m/z 558(2) $[M]^+$, 543(28) $[M - \text{Me}]^+$, and 481(100%) $[M - \text{Ph}]^+$.

Crystallography.—Crystallographic measurements were made on crystals sealed under nitrogen in glass capillaries, using a CAD4 diffractometer operating in the ω — 2θ scan mode with graphite-monochromated Mo-K_α radiation ($\lambda = 0.710 69 \text{ \AA}$) as previously described.⁶ The structures were solved *via* standard heavy-atom procedures and refined using full-matrix least-squares methods,⁷ with scattering factors calculated using data from ref. 8. Pyridine rings in compound (2) and phenyl groups in (2) and (3) were treated as rigid hexagons (C—C 1.395 Å, C—C—C 120°), with hydrogen atoms included at a fixed distance (C—H 0.96 Å). Data were corrected for empirical absorption.

Crystal data for compound (2). $\text{C}_{96}\text{H}_{86}\text{N}_2\text{O}_8\text{Si}_6\text{Ti}$, $M = 1 612.236$, monoclinic, $a = 19.397(7)$, $b = 17.369(5)$, $c = 27.094(11) \text{ \AA}$, $\beta = 108.13(3)^\circ$, $U = 8 674.96 \text{ \AA}^3$, space group $C_{2/c}$, $Z = 4$, $D_c = 1.23 \text{ g cm}^{-3}$, $\mu(\text{Mo-K}_\alpha) = 1.98 \text{ cm}^{-1}$, $F(000) = 3 368$.

Total data recorded 2 724 ($1.5 < \theta < 25.0^\circ$, $\pm h$, $\pm k$, $\pm l$), 5 309 unique reflections, 3 432 observed [$I > 1.5\sigma(I)$]. Final $R = 0.0595$, $R' = 0.0699$ for 438 parameters, $w = [\sigma^2(F) + 0.000 605 F_o^2]^{-1}$. Final atomic positional parameters are given in Table 4.

Crystal data for compound (3). $\text{C}_{97.5}\text{H}_{87}\text{Li}_2\text{N}_3\text{O}_9\text{Si}_6\text{Zr}$, $M = 1 717.425$, triclinic, $a = 14.251(3)$, $b = 14.393(4)$, $c = 24.982(5) \text{ \AA}$, $\alpha = 96.06(2)$, $\beta = 108.85(2)$, $\gamma = 114.38(2)^\circ$, $U = 4 243.84 \text{ \AA}^3$, space group = $P\bar{1}$, $Z = 2$, $D_c = 1.35 \text{ g cm}^{-3}$, $\mu = 2.67 \text{ g cm}^{-1}$, $F(000) = 1 794$.

Total data recorded 9 802 ($1.5 < \theta < 25.0^\circ$, $\pm h$, $\pm k$, $\pm l$), 9 637 unique reflections, 6 499 observed [$I > 1.5\sigma(I)$]. Final $R = 0.0594$, $R' = 0.0689$ for 1 037 parameters, $w = [\sigma^2(F) +$
