PAPER

Switch the triplet excited state of the C<sub>60</sub>-dimethylaminostyryl bodipy dyads/triads

Ling Huang and Jianzhang Zhao\*

Received (in XXX, XXX) Xth XXXXXXXXXX 20XX, Accepted Xth XXXXXXXXXX 20XX

DOI: 10.1039/b000000x

In order to switch the triplet excited states in organic compounds, dimethylaminostyryl Bodipy-C<sub>60</sub> dyads and triads were prepared. The triplet excited states of the compounds were switched with acid/base, the mechanism was studied with nanosecond time-resolved transient difference absorption spectroscopy. The visible light-harvesting Bodipy antennas are the electron or singlet energy donor, whereas C<sub>60</sub> moiety is the electron/singlet energy acceptor, as well as the spin converter to produce triplet excited states. Our strategy of triplet state switching is to control either the photoinduced electron transfer (PET) or the singlet state energy transfer (EnT) from the antenna to C<sub>60</sub> moiety, by protonation of the dimethylaminostyryl Bodipy unit. Population of the triplet state was observed for the dyads with mono(4-dimethylaminostyryl) substituents on Bodipy antenna in nonpolar solvent such as toluene ( $\tau_T = 168.6 \mu s$ ). Formation of the charge transfer state (CTS) in polar solvent quenches the triplet excited state ( $\tau_T < 10 ns$ ). In the presence of acid, the dimethylaminostyryl Bodipy moiety is protonated, thus the electron transfer (ET) was inhibited. The cascade acid-activated EnT and the intersystem crossing (ISC) of C<sub>60</sub> produce the triplet excited state. For the dyad and the triads with bis(4-dimethylaminostyryl) substituents on Bodipy antenna, the antenna S<sub>1</sub> state energy level is lower than the S<sub>1</sub> state energy level of C<sub>60</sub>, thus no EnT to C<sub>60</sub> exist, and no triplet state was produced upon selectively excitation into the Bodipy moiety. With protonation of the aminostyryl substituents, the S<sub>1</sub> state energy level of the antenna is promoted to be higher than S<sub>1</sub> state of C<sub>60</sub> moiety, as a result EnT is activated and triplet state is produced. In all the compounds the triplet excited state is localized on the dimethylaminostyryl Bodipy moiety, not on the C<sub>60</sub> moiety. The triplet state switching was conveyed to the singlet oxygen (<sup>1</sup>O<sub>2</sub>) photosensitizing ability of the compounds, and the variation of the singlet oxygen quantum yield,  $\Phi_{\Delta}$ , is from 1.9% to 73%.

## Introduction

Triplet photosensitizers are important in photocatalysis,<sup>1-4</sup> molecular devices,<sup>5-6</sup> and more recently in triplet-triplet annihilation upconversion.<sup>7-11</sup> Different from the study of *singlet* excited states, study on *triplet* excited state of organic chromophores is rare.<sup>12</sup> Switching of the *singlet* excited state leads to many applications, such as fluorescent molecular sensors,<sup>13-15</sup> visible light-harvesting molecular arrays, etc.<sup>16-19</sup> The mechanisms for switching of singlet excited states include fluorescence resonance energy transfer (FRET),<sup>13a-13d</sup> photoinduced through-bond energy transfer (TBET),<sup>13e,13f</sup> photoinduced electron transfer (PET) and photoinduced intramolecular charge transfer (ICT), etc.<sup>13g</sup> It is highly desired to develop methodologies for controlling of the positioning of triplet state in a multichromophore molecule.

Previously amino-containing bromo-aza Bodipy was studied as acid-activatable photodynamic therapeutic (PDT) reagents.<sup>20</sup> PET mechanism is responsible for the acid-activated OFF and ON state of the photosensitizers to produce triplet excited state, thus

the ability to sensitizing singlet oxygen (<sup>1</sup>O<sub>2</sub>). Bodipy dyads were also studied as molecular devices for modulation of triplet state in which the direction of FRET can be controlled by addition of acid.<sup>5,6</sup> In these studies, however, the triplet excited state manifolds were not studied in detail with nanosecond time-resolved transient difference absorption spectroscopy.<sup>12</sup> Moreover, it is clear that more switching approaches should be explored for switching of the triplet states in organic compounds.

Herein we studied the switching of triplet excited state of C<sub>60</sub>-styryl Bodipy dyads/triads by controlling either the photoinduced intramolecular electron transfer (ET) or energy transfer (EnT).<sup>13c</sup> In the dyads **B-1** and **B-2**, and the triads **B-3** and **B-4** (Scheme 1-2), the Bodipy moieties are visible light-harvesting antennas and electron donor or singlet energy donor; C<sub>60</sub> moiety is the electron acceptor and singlet energy acceptor, as well as the intramolecular spin converter.<sup>12</sup> Bodipy moieties show strong absorption of visible light, but the intersystem crossing (ISC) is non-efficient. The contrary is true for C<sub>60</sub> moiety, i.e. the ISC is efficient (close to unity) but its visible light-absorption is poor. Considering the singlet energy levels of the antenna and C<sub>60</sub>

moiety, RET is possible for **B-1** and **B-3**, thus triplet excited state can be produced. In **B-2** and **B-4**, however, the  $S_1$  state energy level of the antenna is presumably lower than  $C_{60}$ , thus RET is impossible; but the EnT can be activated by protonation. Thus in the presence of acid, triplet state production was observed with **B-2** and **B-4**.

The visible light-harvesting antenna in **B-1** – **B-4** were selected so that either the ET or the EnT to the  $C_{60}$  moieties can be switched by acid, i.e. protonation of aminostyryl Bodipy moiety. The ET and singlet/triplet EnT were investigated with steady state and nanosecond time-resolved spectroscopy, as well as electrochemical studies. For all the dyads and the triads, the  $T_1$  state is localized on the styryl Bodipy moiety, not on  $C_{60}$  moiety. This conclusion is based on the nanosecond time-resolved transient difference absorption spectroscopy. We show that the  $^1O_2$  production with the dyads can be modulated by addition of acid and base.

## Results and Discussions

### Molecular design and synthesis

The Bodipy moiety was selected as the visible light-harvesting antenna, due to its excellent photophysical properties, such as strong absorption of visible light, high fluorescence quantum yields (less non-radiative decay of the singlet excited state), and feasible derivatization.<sup>14,19,21</sup> Aminostyryl Bodipy moiety in **B-2** and **B-4** show lower  $S_1$  state energy level than the  $C_{60}$  moiety, thus EnT is impossible in **B-2** and **B-4**.<sup>12,22-27</sup> As a result, population of the triplet excited state in **B-2** and **B-4** will be non-efficient, upon selectively excited into the Bodipy antenna. In the

presence of acid such as trifluoroacetic acid (TFA), however, the amino group will be protonated, thus the  $S_1$  state energy level of the antenna in **B-2** and **B-4** will be promoted, to be higher than that of  $C_{60}$ , thus EnT become possible, as a result, triplet excited state will be produced by the protonated **B-2** and **B-4**. For **B-1** and **B-3**, the  $S_1$  state energy level of the Bodipy antenna is higher than that of  $C_{60}$ . However, ET to  $C_{60}$  may quench the triplet excited state. In the presence of TFA, ET will be inhibited and the RET will be activated, as a result, triplet excited state can be produced by the protonated **B-1** and **B-3**. **B-3** and **B-4** are Bodipy- $C_{60}$  triads, which show broadband absorption in visible region.<sup>29</sup>

The preparation of the visible light-antennas are based on routine derivatization methods of Bodipy.<sup>14,19</sup> Condensation of the Bodipy with 4-dimethylaminobenzenealdehyde gives the Bodipy antenna which show absorption at 600 nm or 700 nm, dependent on the number of the substituents.<sup>30</sup> The Bodipy antenna was linked to  $C_{60}$  moiety by the Prato reaction. For triads **B-3** and **B-4**, Suzuki cross coupling reaction was used to prepare the broadband visible light-harvesting antenna and Cu(I)-catalyzed Click reaction was used to link the Bodipy and the dimethylamino styryl Bodipy together.<sup>31,32</sup> All the compounds were obtained in moderate to satisfactory yields.

### UV–Vis absorption and fluorescence emission spectra

The UV–Vis absorption of the compounds were studied (Fig. 1). **B-1** shows strong absorption at 622 nm, which is due to the dimethylamino styryl Bodipy moiety. **B-2** shows red-shifted absorption at 712 nm, due to the bis(4'-dimethylaminostyryl)

**Scheme 1** Synthesis of the  $C_{60}$ -dimethylaminostyryl Bodipy dyads **B-1** and **B-2** and the reference compounds. Key: (a) 4-*N,N*-dimethylbenzaldehyde, toluene, acetic acid, piperidine, reflux, 4 h in Ar; (b) the same to (a); (c) 4-formylphenylboronic acid,  $K_2CO_3$ ,  $Pd(PPh_3)_4$ ; (d) the same to (c); (e) Sarcosine, fullerenes, toluene; reflux; (f) the same to (e); (g) Phenylboronic acid,  $K_2CO_3$ ,  $Pd(PPh_3)_4$ ; (h) the same to (g).

**Scheme 2** Synthesis of the  $C_{60}$ -dimethylaminostyryl Bodipy triads **B-3** and **B-4** and the reference compounds. (i) Phenylboronic acid,  $K_2CO_3$ ,  $Pd(PPh_3)_4$ ; (ii) Sarcosine, fullerenes, toluene.

substituted Bodipy moiety. The absorption spectra is almost independent on the solvent polarity. The fluorescence emission of the dyads were also studied. For **B-1**, the fluorescence is at 660 nm (in toluene, Fig. 1b). The emission band was red-shifted to 674 nm in dichloromethane (DCM). The emission profile is similar to the reference **B-5** (see ESI†, Fig. S58). The  $S_1$  state energy of the Bodipy antenna is approximated as 1.88 eV with the emission wavelength, which is higher than the  $C_{60}$  moiety (1.76 eV).<sup>23</sup> Thus photoinduce RET is possible in **B-1**.

The emission band of **B-2** is at 770 nm in DCM. Thus the  $S_1$  state energy of the Bodipy antenna in **B-2** can be approximated as 1.61 eV. The  $S_1$  state energy level of the antenna in **B-2** is lower than the  $C_{60}$  moiety (1.76 eV),<sup>23</sup> as a result, the RET to  $C_{60}$  in **B-2** may be frustrated. The emission of **B-2** is more sensitive to the solvent polarity, thus more significant ICT is proposed for the antenna in **B-2**. The emission profile is similar to the reference compounds **B-6** (see ESI†, Fig. S59). The absorption and the fluorescence of the reference compounds **B-5** and **B-6** were also studied (see ESI†, Fig. S58-S59). The results are similar to that of **B-1** and **B-2**, respectively.

**Fig. 1** (a) UV-Vis absorption spectra of **B-1** in toluene and DCM and (b) the corresponding emission spectra of **B-1**.  $\lambda_{ex}$  = 600 nm,  $A$  = 0.618, (c) UV-Vis absorption spectra of **B-2** in toluene and DCM and (d) the corresponding emission spectra of the **B-2**.  $\lambda_{ex}$  = 680 nm,  $A$  = 0.559.  $c$  =  $1.0 \times 10^{-5}$  M for UV-Vis absorption spectra measurement. 20 °C.

**Fig. 2** (a) UV-Vis absorption spectra of **B-3** in DCM and toluene and (b) the corresponding emission spectra of **B-3**,  $\lambda_{\text{ex}} = 590$  nm,  $A = 0.60$ , (c) UV-Vis absorption spectra of **B-4** and (d) the corresponding emission spectra of **B-4**,  $\lambda_{\text{ex}} = 486$  nm,  $A = 0.51$ ,  $c = 1.0 \times 10^{-5}$  M for the UV-Vis absorption spectral measurement. 20 °C.

Two major absorption bands in visible spectral region were observed for triad **B-3** (Fig. 2a), which are attributed to the Bodipy and the dimethylaminostyryl Bodipy moiety in **B-3**, respectively. Emission of the Bodipy moiety was completely quenched in **B-3**, only an emission band at 675 nm was observed (Fig. 2b), which is due to the dimethylaminostyryl Bodipy moiety. This result indicated singlet EnT. This property was supported by the emission of the antenna **B-7** (see ESI†, Fig. S61). Broadband absorption was also observed for **B-4** (Fig. 2c). The emission of **B-4** is red-shifted as compared with that of **B-3**. For **B-4**, residual emission at 516 nm was observed.

**Fig. 3** Fluorescence of dyads **B-1** and triad **B-3** and the reference compounds. (a) Fluorescence emission spectra of **B-1** and **B-5**,  $\lambda_{\text{ex}} = 575$  nm ( $A = 0.42$  for both **B-1** and **B-5**). (b) Fluorescence emission spectra of **B-3**, **B-7** and **B-9**,  $\lambda_{\text{ex}} = 480$  nm ( $A = 0.27$  for **B-3**, **B-7** and **B-9**).  $c = \text{ca. } 1.0 \times 10^{-5}$  M in DCM, 20 °C.

The fluorescence emission of **B-1** and the visible light-harvesting antenna **B-5** was compared (Fig. 3). The strong fluorescence of **B-5** ( $\Phi_{\text{F}} = 47\%$ ) was quenched in **B-1** ( $\Phi_{\text{F}} = 0.1\%$ ). For **B-2**, similar results were observed (see ESI†, Fig. S70a). Similar results were observed for **B-3**, the reference compounds (Fig. 3b) and **B-4** (see ESI, Fig. S70b). These quenching of the fluorescence of the energy donor in the dyads or

triads indicated EnT or ET, with the  $\text{C}_{60}$  as the energy or electron acceptor.<sup>23,33</sup> Similarly, the emission of **B-6** was substantially quenched in **B-2** (see ESI†, Fig. S70a). Same quenching effect was also found for **B-9** and **B-8** in **B-4** (see ESI†, Fig. S70).

**Fig. 4** Comparison of the fluorescence excitation spectra and UV-Vis absorption spectra of **B-3'** or **B-3** in different solvents. (a) **B-3'** in toluene; (b) **B-3'** in DCM,  $\lambda_{\text{em}} = 680$  nm; (c) **B-3** in toluene and (d) **B-3** in DCM,  $\lambda_{\text{em}} = 700$  nm.  $c = 1.0 \times 10^{-5}$  M, 20 °C.

The singlet state EnT in the compounds were studied with the fluorescence excitation spectra, exemplified with triad **B-3** and **B-3'** (Fig. 4).<sup>32</sup> In toluene, the excitation spectrum of **B-3** (or **B-3'**) is superimposable with the UV-Vis spectrum (Fig. 4a and 4c). Thus the singlet EnT from the Bodipy moiety to the styryl-Bodipy moiety in **B-3** and **B-3'** is close to unity (95% and 96%). Moreover, the singlet EnT between the Bodipy and the styrylBodipy part takes place first, not the EnT between Bodipy and the  $\text{C}_{60}$  moiety, otherwise no excitation band at 531 nm should be observed for **B-3**. In polar solvent such as DCM, the comparison of the excitation spectrum with the UV-Vis absorption spectrum indicated that the energy transfer is slightly less efficient (85% and 88%, Fig. 4b and 4d). This may be due to the more significant ET in polar solvents.<sup>23</sup> The emission of **B-4** is too weak to be used for excitation spectra study. Therefore the fluorescence excitation spectra of **B-8** were studied (see ESI†, Fig. S69). The singlet EnT efficiency is 75% in toluene, and 66% in DCM.

#### Changes of the UV-Vis absorption and fluorescence spectra upon addition of acid

Protonation of the aminostyryl Bodipy in the dyads and the triads will change the absorption and fluorescence emission wavelength of the antennas.<sup>6,28</sup> Thus, the UV-Vis absorption spectra and the fluorescence spectra of the compounds were studied upon addition of trifluoroacetic acid (TFA, Fig. 5). For **B-1**, the absorption band at 623 nm decreased and a new absorption band at 573 nm developed upon addition of TFA. Accordingly, the emission band is blue-shifted from 674 nm to 591 nm upon addition of TFA (Fig. 5a and 5b). The changes can be better

studied with the antenna alone, i.e. **B-5** (see ESI†, Fig. S63) because the fluorescence of **B-5** is much stronger than that of **B-1**.

For **B-2**, the absorption band at 712 nm decreased upon addition of TFA, and a new absorption band at 627 nm developed concomitantly (Fig. 5c), accordingly the fluorescence band shows blue-shifting from 770 nm to 644 nm (Fig. 5d). Based on

**Fig. 5** Variation of the UV-Vis absorption spectra and the fluorescence emission spectra of **B-1** and **B-2** upon protonation with trifluoroacetic acid (TFA). (a) **B-1** with increasing TFA added and (b) the corresponding emission spectra of **B-1** ( $\lambda_{\text{ex}} = 540$  nm) upon addition of TFA; (c) **B-2** with increasing TFA added and (d) the corresponding emission spectra changes of **B-2** ( $\lambda_{\text{ex}} = 600$  nm) upon addition of TFA. The aliquots of TFA added are 0.4  $\mu\text{L}$ , 1  $\mu\text{L}$ , 2  $\mu\text{L}$ , 3  $\mu\text{L}$ , 4  $\mu\text{L}$ , 5  $\mu\text{L}$ , 10  $\mu\text{L}$ , 20  $\mu\text{L}$  and of 1 M TFA in  $\text{CH}_2\text{Cl}_2$ ,  $c = 1.0 \times 10^{-5}$  M in DCM, 20  $^\circ\text{C}$ .

**Fig. 6** Variation of the UV-Vis absorption spectra and the fluorescence emission spectra of **B-3** and **B-4** upon protonation with addition of TFA. (a) **B-3** with increasing TFA added and (b) the corresponding emission spectra changes of **B-3** ( $\lambda_{\text{ex}} = 540$  nm) upon addition of the TFA. (c) **B-4** with increasing TFA added and (d) the corresponding emission spectra changes of **B-4** ( $\lambda_{\text{ex}} = 600$  nm) upon addition of TFA. In  $\text{CH}_2\text{Cl}_2$ , ( $1.0 \times 10^{-5}$  M; 20  $^\circ\text{C}$ ). The aliquots of TFA added are 0.4  $\mu\text{L}$ , 1  $\mu\text{L}$ , 2  $\mu\text{L}$ , 3  $\mu\text{L}$ , 4  $\mu\text{L}$ , 5  $\mu\text{L}$ , 10  $\mu\text{L}$ , 20  $\mu\text{L}$  of 1 M TFA in  $\text{CH}_2\text{Cl}_2$  ( $c = 1.0 \times 10^{-5}$  M in DCM, 20  $^\circ\text{C}$ ).

these blue-shifting in the UV-Vis absorption and fluorescence emission spectra, we propose that the EnT from the styryl Bodipy part to the  $\text{C}_{60}$  moiety can be switched on by addition of TFA. The response of **B-6** to addition of TFA was studied, similar UV-Vis absorption and fluorescence emission spectral changes were observed (see ESI†, Fig. S63). Similar blue shifting were observed in the UV-Vis absorption and the fluorescence emission spectra of the triads **B-3** and **B-4** (Fig. 6). The response of **B-7** and **B-8** to addition of TFA was studied, similar UV-Vis absorption and fluorescence emission spectral changes were observed (see ESI†, Fig. S64).

### Nanosecond time-resolved transient difference absorption spectra

In order to study the triplet excited state of the compounds, the nanosecond time-resolved transient difference absorption spectra of the compounds were studied (Fig. 7). The lifetime of the transient is usually the lifetime of the triplet state.<sup>12</sup> For **B-1**, bleaching band at 622 nm was observed upon pulse laser excitation in toluene (Fig. 7a), where the dimethylaminostyryl Bodipy shows strong steady state absorption. Thus the triplet excited state is localized on the styryl Bodipy moiety, not the  $\text{C}_{60}$  moiety. The triplet state lifetime was determined as 168.6  $\mu\text{s}$ . Therefore, different from the direction of the singlet EnT, i.e. RET process, a reversed triplet EnT from the  $\text{C}_{60}$  moiety to the styryl Bodipy takes place. Such a ping-pong EnT was observed for  $\text{C}_{60}$ -chromophore hybrids.<sup>29,34,35</sup>

**Fig. 7** Nanosecond time-resolved transient difference absorption of **B-1** in different solvents. (a) Transient absorption spectra and (b) decay trace at 580 nm in deaerated toluene; (c) Transient absorption spectra with 20  $\mu\text{L}$  of 1 M TFA added and (d) the corresponding decay trace at 580 nm, in deaerated dichloromethane. Excited with nanosecond pulsed laser at  $\lambda_{\text{ex}} = 532$  nm.  $c = 1.0 \times 10^{-5}$  M, 20  $^\circ\text{C}$ .

In polar solvent, such as DCM, no transient signal was detected, which can be attributed to ET, which is usually more favored in polar solvent than that in non-polar solvent (see later electrochemical studies).<sup>23</sup> In the presence of TFA, bleaching band at 573 nm was observed (Fig. 7c), which is in agreement with the steady-state absorption spectra of **B-1** in acidic DCM (Fig. 7). The new triplet state is localized on the protonated

Bodipy ligand, but the triplet excited state is different from that for **B-1** in toluene. Note the transient difference absorption profile in 600 – 850 nm is different for Fig. 7a and 7b. The triplet state lifetime was determined as 4.4  $\mu\text{s}$ . The observation of TA signal in acidic DCM is due to the inhibited ET by the protonation, thus the inhibition of the ET process.

The nanosecond time-resolved transient difference absorption spectra of **B-2** were also studied (Fig. 8). No transient spectra was observed in toluene. Electron transfer is usually difficult to take place in non-polar solvents, such as toluene.<sup>23</sup> This result can be attributed to the lower  $S_1$  state energy level of antenna (1.67 eV) than the  $S_1$  state of  $C_{60}$  (1.76 eV),<sup>23</sup> i.e. there is no RET for **B-2** in toluene, as a result, no triplet state can be produced. In order to validate this conclusion,  $^1\text{O}_2$  photosensitizing study was performed, no  $^1\text{O}_2$  production was observed for **B-2** in toluene (see ESI†, Fig. S78–79).

**Fig. 8** Nanosecond time-resolved transient difference absorption spectra of **B-2**. (a) Transient difference absorption spectra and (b) the decay trace at 630 nm. In deaerated DCM with 20  $\mu\text{L}$  of 1 M TFA added.  $\lambda_{\text{ex}} = 532 \text{ nm}$  ( $c = 1.0 \times 10^{-5} \text{ M}$ , 20 °C).

In DCM, no transient spectra was observed. In DCM with TFA added, however, a bleaching band at 627 nm was observed (Fig. 8a), which is in agreement with the steady state absorption of the protonated **B-2**. Thus the triplet state is localized on the protonated Bodipy ligand. A triplet state lifetime of 74.8  $\mu\text{s}$  was observed (Fig. 8b). Based on the nanosecond TA data, we propose the EnT in **B-2** was modulated by addition of acid, i.e. protonation of the aminostyryl Bodipy antenna. This is different from **B-1**, for which the ET was inhibited by addition of TFA.

Similar transient absorption spectra were observed for **B-3** (Fig. 9) as compared with that of **B-1**. Bleaching band at 625 nm was observed upon pulsed laser excitation in toluene. Positive

transient absorption in the region of 670 – 850 nm region were observed. Exceptionally long triplet state lifetime of 333.7  $\mu\text{s}$  was determined. These features are close to that of **B-1** under the same conditions. Therefore, the triplet state is localized on styryl Bodipy part, not on the  $C_{60}$  moiety in **B-3**. In DCM with TFA added, a bleaching band at blue-shifted position of 571 nm was observed for **B-3** (Fig. 9c), which is in agreement with the steady state absorption of the protonated amino styryl Bodipy antenna in **B-3** (Fig. 6a). Thus the triplet state is localized on the protonated amino styryl Bodipy moiety in **B-3**. In this case a 'ping-pong' singlet/triplet energy transfer takes place.<sup>28</sup>

**Fig. 9** Nanosecond time-resolved transient difference absorption of **B-3** in different solvents. (a) Transient difference absorption spectra and (b) decay trace at 620 nm in deaerated toluene; (c) Transient difference spectra of **B-3** with 20  $\mu\text{L}$  of 1 M TFA added and (d) the corresponding decay trace at 580 nm, in deaerated DCM.  $\lambda_{\text{ex}} = 532 \text{ nm}$ , ( $c = 1.0 \times 10^{-5} \text{ M}$ , 20 °C)

Transient absorption spectra were observed for **B-3'** (Fig. 10) as compared with that of **B-1** and **B-3**. Bleaching band at 600 nm was observed upon pulsed laser excitation in toluene. Positive transient absorption in the region of 650 – 850 nm region were observed (Fig. 10a). A triplet state lifetime of 140.1  $\mu\text{s}$  was determined (Fig. 10b). These features are close to that of **B-1** under the same conditions. Therefore, the triplet state is localized

on the styryl Bodipy part, not on the Bodipy moiety or C<sub>60</sub> moiety in **B-3'**.

Different from **B-1** and **B-3**, transient absorption spectra were observed for **B-3'** in DCM (Fig. 10c). The feature of the transient spectra are similar to that in toluene. A triplet state lifetime of 100.7  $\mu$ s was observed (Fig. 10d). The slightly decreased triplet state lifetime in DCM than that in toluene may be due the enhanced ET.<sup>23</sup> However, we propose that photo-induced ET is not significant, otherwise the triplet state will be quenched, like in **B-1** and **B-3**. The thermodynamic driving force for photoinduced

**Fig. 10** Nanosecond time-resolved transient difference absorption spectra of **B-3'** in different solvents. (a) Transient spectra and (b) the corresponding decay trace at 620 nm. In deaerated toluene. (c) Transient spectra in deaerated dichloromethane and (d) the corresponding decay trace at 620 nm; (e) Transient spectra of **B-3'** in deaerated DCM with 20  $\mu$ L of 1 M TFA added and (f) the corresponding decay trace at 570 nm.  $\lambda_{\text{ex}} = 532$  nm,  $c = 1.0 \times 10^{-5}$  M, 20  $^{\circ}\text{C}$ .

electron transfer was calculated with the Weller equation. **B-3** is with slightly larger driving force ( $\Delta G^{\circ}_{\text{cs}} = -0.68$  eV) than **B-3'** ( $\Delta G^{\circ}_{\text{cs}} = -0.65$  eV). The charge transfer state energy level ( $E_{\text{CTS}} = 1.26$  eV) is higher than triplet state energy level ( $T_1 = 1.24$  eV by DFT calculated. In DCM). But for **B-1**, the charge transfer state energy level ( $E_{\text{CTS}} = 1.14$  eV) is lower than triplet state energy level, thus it is effective for quenching the triplet state though electron transfer. In toluene, the Gibbs free energy was calculated for **B-3** ( $\Delta G^{\circ}_{\text{cs}} = -0.18$  eV) and **B-3'** ( $\Delta G^{\circ}_{\text{cs}} = +0.17$  eV). From the above analysis, it can be deduced that the electron transfer of **B-3** is more significant than **B-3'**.

In DCM with TFA added, a bleaching band at blue-shifted position of 557 nm was observed for **B-3'** (Fig. 10e), which is in agreement with the steady state absorption of the protonated amino styryl Bodipy antenna in **B-3'**. Thus the triplet state is

localized on the protonated amino styryl Bodipy moiety in **B-3'**, not on the Bodipy or the C<sub>60</sub> moiety. In this case a 'ping-pong' singlet/triplet EnT takes place.<sup>28</sup> Note the triplet state lifetime is different from the neutral **B-3'**. The transient spectra of **B-3'** indicated that the ET is less significant as compared to that of **B-1** and **B-3**. We attributed this difference in ET capability to the different structure of the antenna. In **B-3'**, the distance between the electron donor and C<sub>60</sub> moiety (electron acceptor) is larger than that in **B-1**.

For **B-4**, no transient signal can be detected and no  $^1\text{O}_2$  produced in both toluene and DCM (Fig. S78-79). It is most likely due to the unmathced S<sub>1</sub> state of the antenna and the C<sub>60</sub> moiety. In DCM with TFA added, bleaching band at 627 nm was detected (Fig. S83a). Thus the triplet excited state is localized on the aminostyryl Bodipy antenna, not on the C<sub>60</sub> moiety. The production of triplet excited state in the presence of TFA is due to the increased energy level of the S<sub>1</sub> state of the antenna, thus the acid-activated EnT to C<sub>60</sub> occurred. The results of the triads **B-3** and **B-4** indicated that the RET from Bodipy to C<sub>60</sub> is not taking place, rather the sequential Bodipy  $\rightarrow$  aminostyryl Bodipy  $\rightarrow$  C<sub>60</sub> process is taking place in the triads.

### Electrochemical studies

The electrochemical property of **B-1** and reference **B-5** was studied in DCM (Fig. 11 and Table 2. for **B-3**, **B-4** and reference compounds, see ESI†, Fig. S71-S74 and Table 2). For **B-5**, there are two reversible oxidation waves at +0.34 V, +0.66 V, and one reversible reduction wave at -1.41 V. For **B-1**, in the anodic scan, two reversible oxidation waves at around +0.35 V, +0.67 V were observed. In the cathodic scan, two reversible reduction potential was observed for **B-1** (-0.97 eV, -1.38 eV), which are due to fullerene. In order to study electron transfer from dimethylaminostyryl Bodipy to fullerene, the Gibbs free energy ( $\Delta G^{\circ}_{\text{cs}}$ ) was calculated. From the  $\Delta G^{\circ}_{\text{cs}}$  analysis, some results have been found. In polar solvent, the free energy changes of **B-1** in CH<sub>2</sub>Cl<sub>2</sub> ( $\Delta G^{\circ}_{\text{cs}} = -0.74$  eV) is larger than that in nonpolar solvent ( $\Delta G^{\circ}_{\text{cs}} = -0.24$  eV in toluene). Therefore the triplet state is unlikely to be observed in the polar solvent. For **B-2**, the free energy changes is large in DCM ( $\Delta G^{\circ}_{\text{cs}} = -0.74$  eV), thus the fluorescence emission is effectively quenched by photoinduced intramolecular electron transfer (Fig. 1). In nonpolar solvent toluene, the S<sub>1</sub> energy level is 1.67 eV for dimethylaminodistyryl Bodipy lower than C<sub>60</sub> (1.76 eV), therefore no triplet state

was observed for **B-2** because RET can not occur. Similar results were observed for **B-3** and **B-4** (Table 2, 3 and Fig. S71-S74).

These electrochemical data can be used to explain the triplet state properties of the dyads/triads in solvent with different polarity. For example, the free energy changes for ET in polar solvent is usually large than that in nonpolar solvent such as toluene. This is true for **B-1** and **B-2**, etc. Upon protonation, the ET process was prohibited, thus triplet state can be observed for the dyads/triads.

#### Application of the acid-activated triplet state production: singlet oxygen (<sup>1</sup>O<sub>2</sub>) photosensitizing

With the nanosecond time-resolved transient difference absorption spectroscopy, we demonstrated that the production of the triplet excited state by the dyads and the triads can be switched by acid. Therefore, the switching of the <sup>1</sup>O<sub>2</sub> photosensitizing ability of the dyads and the triads were studied (Fig. 12).<sup>12</sup> 1,3-diphenylisobenzofuran (DBPF) was used as the <sup>1</sup>O<sub>2</sub> scavenger. Thus the absorption of DBPF at 414 nm can be followed to monitor the kinetics of the <sup>1</sup>O<sub>2</sub> production of the dyads and the triads upon visible light photoirradiation.<sup>36,37</sup>

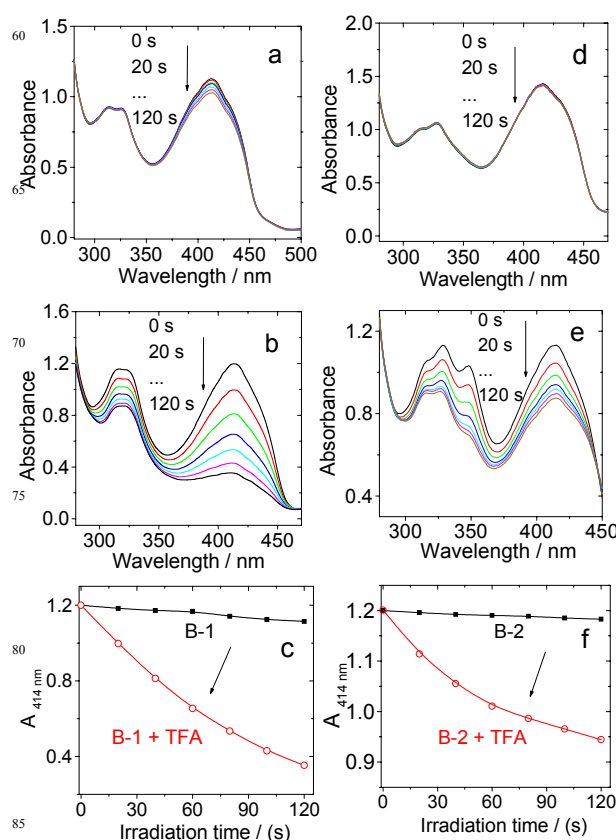

For **B-1**, no <sup>1</sup>O<sub>2</sub> production can be observed in the absence of acid (TFA) (Fig. 12a). In the presence of acid (TFA, Fig. 12b), the absorbance of the solution at 414 nm decrease sharply upon photoexcitation, indicating that <sup>1</sup>O<sub>2</sub> was produced in a significant fast kinetics, i.e. the triplet state production of **B-1** is switched ON. Note DPBF alone is stable under the same condition (see ESI†, Fig. S95), thus the <sup>1</sup>O<sub>2</sub> photosensitizing was confirmed.

Similar studies were applied for **B-3** and **B-4** (see ESI†, Fig. S94). No <sup>1</sup>O<sub>2</sub> was produced in DCM upon photoexcitation. In the presence of TFA, photosensitization <sup>1</sup>O<sub>2</sub> was observed. This observation is in agreement with the nanosecond time-resolved transient absorption spectra of **B-3** and **B-4**. Interestingly, no modulation on the <sup>1</sup>O<sub>2</sub> photosensitizing of **B-3'** by addition of acid was observed. This phenomena is in agreement with the nanosecond time-resolved transient difference absorption spectra of **B-3'**, i.e. triplet state production was observed for **B-3'** in DCM, as well as in DCM with TFA added (see ESI†, Fig. S94). Thus the <sup>1</sup>O<sub>2</sub> production of the triplet photosensitizers can be directly correlated to the triplet state production of the dyads and triads. <sup>1</sup>O<sub>2</sub> photosensitizing of **B-4** can be switched by addition

(c) Absorbance of DPBF at 414 nm changes in the absence and in the presence of TFA ( $\lambda_{ex}$  = 588 nm). UV-Vis absorption spectral changes with **B-2** as photosensitizer, (d) in the absence of TFA and (e) in the presence of acid, (f) in absorbance of DPBF at 414 nm changes in the absence and in the presence of TFA ( $\lambda_{ex}$  = 646 nm). <sup>c</sup> [photosensitizers] =  $1.0 \times 10^{-5}$  M in CH<sub>2</sub>Cl<sub>2</sub>, 20 °C.

of acid (see ESI, Fig. S94), which is in agreement with the study of the triplet state production of **B-4** by the nanosecond time-resolved transient difference absorption spectra. More significant is that switching of the triplet state of photosensitizers is reversible by adding acid and base alternatively. When the acid was neutralized with base, the photophysical properties of the photosensitizers fully recovered (see ESI†, Fig. S83-93).

The  $^1\text{O}_2$  quantum yields ( $\Phi_\Delta$ ) of the dyads and triads were measured in the absence and presence of TFA. For **B-1**, the  $\Phi_\Delta$  value is 1.9% in the absence of TFA. In the presence of TFA,  $\Phi_\Delta$  increased to 73% (Table 4). Similar switching effect was observed for **B-2-4**. For **B-3'**, however, the  $\Phi_\Delta$  value in the absence and in the presence of TFA is 30% and 39%, thus no switching effect of the triplet excited state production was observed for **B-3'**. This finding is in agreement with the nanosecond time-resolved transient difference absorption spectral studies of the compounds (Fig. 9).

<sup>c</sup> Quantum yield of singlet oxygen ( $^1\text{O}_2$ ). For short wavelength excitation, diiodoBodipy was used as standard ( $\Phi_\Delta = 0.82$  in  $\text{CH}_2\text{Cl}_2$ ), for the long wavelength excitation, methylene blue was used as standard ( $\Phi_\Delta = 0.57$  in  $\text{CH}_2\text{Cl}_2$ ).

### Jablonski diagrams: Photophysical processes of the dyads/triads

The photophysical processes of **B-1** were summarized in Scheme 4. Upon selective photoexcitation into the styrylBodipy antenna in **B-1** (Scheme 4a), the singlet excited state of the antenna was produced firstly. Then via intramolecular energy transfer, the singlet excited state of the  $\text{C}_{60}$  moiety was produced. Then via the inherent ISC of  $\text{C}_{60}$ , the triplet state of  $\text{C}_{60}$  moiety was produced. Since the triplet state energy level of the styryl Bodipy is lower than that of  $\text{C}_{60}$  moiety, the intramolecular triplet state energy transfer is envisaged.

The charge transfer state (CTS) is with lower energy level than that of the  $T_1$  state of styrylBodipy, thus the triplet state can be quenched by production of the CTS. In toluene, however, the CTS is with energy level of 1.64 eV, which is higher than that of the triplet state energy level of the styrylBodipy moiety. Thus the triplet state of the styrylBodipy will not be quenched by any CTS. These postulations are in full agreement with the experimental results (Fig. 7). It should be pointed out the triplet state can be produced from the charge recombination process.<sup>23,38</sup>

**Scheme 4.** Simplified Jablonski diagram illustrating the photophysical processes of **B-1** (a) in the absence and (b) in the presence of acid.  $\text{CH}_2\text{Cl}_2$  was used as solvent.  $[\text{C}_{60}\text{-BDP}]$  stands for **B-1**. The localization of the excited state in the dyad was designated with red color and a asterisk. The number of the superscript designated spin multiplicity.

In the presence of **B-1** (Scheme 4b), the dimethylamino group is protonated, thus the CTS energy level will be promoted (data are unavailable due to the interference of  $\text{H}^+$  in the measurement of cyclic voltammetry). Thus, the triplet state of the protonated dimethylamino styrylBodipy moiety will not be quenched by CTS. Thus triplet state was detected for **B-1** even in polar solvents such as dichloromethane (Fig. 7).

**Scheme 5.** Simplified Jablonski diagram illustrating the photophysical processes involved **B-2** (a) in the absence of acid and (b) in the presence of acid.  $[\text{C}_{60}\text{-BDP}]$  stands for **B-2**. The localization of the triplet state in the dyad was designated with red color and a asterisk. The number of the superscript designated the spin multiplicity of the excited state.

The photophysics of **B-2** is slightly different from that of **B-1** (Scheme 5). First, the  $S_1$  state energy level of the dimethylaminostyrylBodipy part is lower than that of  $\text{C}_{60}$ , thus FRET is impossible (Scheme 5a). Second, CTS is with energy level of 0.95 eV, thus any triplet state localized on either the  $\text{C}_{60}$  or the dimethylaminostyrylBodipy will be quenched. This postulation is in agreement with the experimental results that no triplet excited state was observed for **B-2**, either in toluene or in dichloromethane, which is different from that of **B-1**.

In the presence of acid, such as TFA, the dimethylamino group is protonated, thus the  $S_1$  state energy level becomes higher than the  $S_1$  state of the  $\text{C}_{60}$  moiety, as a result the FRET is possible (Scheme 5b). Moreover, upon protonation, the CTS energy level is elevated (exact data are unknown due to the difficulty to record the electrochemical data of the protonated species). Thus triplet state was observed for **B-2** in the presence of TFA (Fig. 8).

## Conclusions

In conclusion, in order to switch the triplet excited states of organic compounds, dimethylaminostyryl Bodipy- $C_{60}$  dyads and triads were prepared. The designing rationales of these compounds are that either the photoinduced electron transfer (ET) or the singlet state energy transfer (EnT) from the visible light-harvesting antenna to  $C_{60}$  moiety can be switched by acid (protonation of the amino styryl moiety).  $C_{60}$  moiety in the dyads/triads is the electron or singlet energy acceptor, and the spin converter. Bodipy units are the visible light harvesting antenna, the singlet energy and electron donor. The triplet state of the compounds was studied in detail with nanosecond time-resolved transient difference absorption spectroscopy. For the dyad with the mono(4'-dimethylaminostyryl) Bodipy antenna, the triplet excited state was quenched by intramolecular EnT in polar solvent. In presence of acid (trifluoroacetic acid), the dimethylaminostyryl Bodipy moiety is protonated, as a result, the ET was inhibited. Therefore the sequential EnT and the intersystem crossing of  $C_{60}$  process produce triplet excited state. For the dyad and the triads with bis(4-dimethylaminostyryl) substituted Bodipy antenna, the lower antenna  $S_1$  state energy level than that of  $C_{60}$  prohibits any RET to  $C_{60}$ , thus no triplet state was produced. In the presence of acid thus protonation of the aminostyryl substituents, the UV-Vis absorption and the fluorescence emission show drastic blue shifting, and the  $S_1$  state energy level of the antenna is increased to be higher than  $S_1$  state of  $C_{60}$  moiety, as a result EnT is activated and triplet state will be produced. In all the compounds the triplet excited state is localized on the dimethylaminostyryl Bodipy moiety, not on the  $C_{60}$  moiety. We proved that the  $^1O_2$  photosensitizing ability of the compounds can be switched by acid (the variation of the singlet oxygen quantum yield can be up to 30-fold). These studies will be useful for development of external stimuli-activatable triplet state production with organic chromophores and for the application of these compounds in activatable photodynamic therapeutic reagents, molecular devices and fundamental photochemistry studies.

## Experimental section

**General Methods.** UV-Vis absorption spectra were taken on a HP8453 UV-Vis absorption spectrophotometer. Fluorescence spectra were recorded on a Shimadzu RF 5301PC spectrofluorometer. Luminescence lifetimes were measured on a OB 920 fluorescence/phosphorescence lifetime spectrometer. For the preparation of the intermediate compounds, please refer to the ESI  $^\dagger$ .

**Compound B-1.** Under Ar atmosphere, a mixture of compound **4** (28.0 mg, 0.05 mmol), fullerene (43.2 mg, 0.006 mmol) and sarcosine (17.8 mg, 0.20 mmol) were dissolved in dry toluene (50 mL). The mixture was refluxed for 12 h. After completion of the reaction, the mixture was cooled to room temperature (RT). After removal of the solvent under reduced pressure, the mixture was purified by column chromatography (silica gel, DCM) to give black solid. MP >250°C Yield: 40.5 mg (62 %).  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.84 (s, 2H), 7.54–7.50 (m, 3H), 7.47–7.45 (m, 3H), 7.33–7.31 (m, 2H), 7.24–7.20 (m, 3H), 6.83 (s, 2H), 6.62 (s, 1H), 5.01 (s, 2H), 4.31 (s, 1H), 3.05 (s,

HRMS (MALDI):  $m/z$  calcd for  $[C_{97}H_{37}BF_2N_4]^+$ : 1306.3079; found 1306.3124.

**Compound B-2.** The compound was prepared with the same methods of **B-1**. **B-2** was purified by chromatography (silica gel, DCM) to give black solid. Yield: 28.8 mg (57 %). MP >250°C.  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.97–7.77 (m, 5H), 7.52–7.44 (m, 5H), 7.35–7.32 (m, 5H), 7.11–7.10 (m, 2H), 6.63–6.53 (m, 5H), 5.04–4.96 (m, 2H), 4.28–4.26 (m, 1H), 2.80 (s, 3H), 1.54 (s, 3H), 1.43 ppm (s, 3H).  $^{13}C$  NMR (100 MHz,  $CDCl_3$ ): 156.3, 154.1, 153.6, 153.4, 147.4, 147.3, 146.7, 146.5, 146.3, 146.2, 146.1, 146.0, 145.8, 145.6, 145.5, 145.4, 145.3, 145.2, 145.1, 144.8, 144.5, 144.4, 144.3, 143.1, 143.0, 142.7, 142.6, 142.5, 142.3, 142.2, 142.1, 142.0, 141.9, 141.8, 141.7, 141.6, 141.5, 141.4, 141.3, 141.2, 140.2, 139.9, 139.5, 137.0, 136.6, 135.9, 135.8, 129.5, 128.9, 128.7, 112.5, 112.3, 112.2, 112.1, 83.6, 70.0, 69.1, 68.1, 40.0, 25.6, 14.7, 12.4 ppm. HRMS (MALDI):  $m/z$  calcd for  $[C_{106}H_{46}BF_2N_5]^+$ : 1437.3814; found 1437.3922.

**Compound B-3.** The preparation procedure is similar to that of **B-1**. **B-3** was purified by chromatography (silica gel, DCM) to give black solid. Yield: (26.0 mg, 49 %). MP >250°C.  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.90 (s, 1H), 7.75 (s, 1H), 7.53–7.50 (m, 3H), 7.24–7.17 (m, 8H), 7.11 (d, 2H,  $J$  = 8.4 Hz), 6.98 (d, 2H,  $J$  = 8.0 Hz), 6.79 (s, 2H), 6.61 (s, 1H), 5.98 (s, 2H), 5.25 (s, 2H), 5.03 (s, 2H), 4.83–4.82 (m, 2H), 4.44–4.42 (m, 2H), 4.31 (s, 1H), 3.05 (s, 6H), 2.88 (s, 3H), 2.56 (s, 6H), 2.51 (s, 3H), 1.44 (s, 3H), 1.42 (s, 6H), 1.27 ppm (s, 3H).  $^{13}C$  NMR (100 MHz,  $CDCl_3$ ): 158.86, 158.24, 155.39, 147.32, 147.29, 146.69, 146.44, 146.29, 146.26, 146.22, 146.17, 146.11, 146.09, 145.93, 145.92, 145.74, 145.56, 145.53, 145.44, 145.36, 145.27, 145.22, 145.17, 145.15, 144.70, 144.52, 144.39, 144.32, 143.75, 143.13, 143.07, 142.98, 142.87, 142.59, 142.56, 142.53, 142.23, 142.17, 142.05, 141.90, 141.89, 141.76, 141.68, 141.52, 141.48, 140.18, 140.13, 139.78, 139.60, 136.16, 135.89, 135.75, 133.74, 131.80, 131.11, 130.43, 129.96, 129.36, 128.79, 127.75, 124.13, 121.25, 118.01, 225.36, 115.00, 83.24, 66.33, 61.99, 49.88, 39.99, 31.93, 29.69, 15.05, 14.63, 14.13, 13.38, 12.97. HRMS (MALDI):  $m/z$  calcd for  $[C_{121}H_{61}B_2F_4N_9O_2]^+$ : 1769.5070; found 1769.4987.

**Compound B-4.** The preparation procedure is similar to that of **B-1**. **B-4** was purified by chromatography (silica gel, DCM) to give black solid. Yield: 23.9 mg (38 %). MP >250°C.  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.90 (s, 2H), 7.68–7.52 (m, 5H), 7.33–7.31 (m, 3H), 7.22–7.18 (m, 5H), 7.12–7.09 (m, 4H), 6.99–6.95 (m, 4H), 6.80–6.69 (m, 5H), 5.98 (s, 2H), 5.25 (s, 2H), 5.00 (s, 2H), 4.83–4.80 (m, 2H), 4.43–4.40 (m, 2H), 4.28 (s, 1H), 3.05 (s, 12H), 2.17 (s, 3H), 2.08 (s, 6H), 1.59 (s, 6H), 1.42 (s, 6H).  $^{13}C$  NMR (100 MHz,  $CDCl_3$ ):  $\delta$  = 158.83, 158.25, 155.40, 147.37, 147.30, 147.27, 146.37, 146.29, 146.24, 146.23, 146.15, 146.12, 146.04, 145.98, 145.95, 145.79, 145.59, 145.53, 145.49, 145.40, 145.36, 145.34, 145.23, 145.18, 145.10, 144.96, 144.92,

144.88, 144.82, 144.77, 144.75, 144.72, 144.54, 144.42, 144.37, 144.35, 144.29, 144.26, 143.75, 143.14, 143.10, 143.07, 143.01, 142.73, 142.65, 142.63, 142.60, 142.55, 142.23, 142.11, 142.07, 141.96, 141.90, 141.75, 141.73, 141.51, 141.44, 140.22, 139.86, 139.35, 135.95, 135.69, 131.76, 129.36, 127.76, 124.15, 121.24, 115.37, 115.01, 66.35, 65.84, 62.01, 49.88, 39.94, 30.94, 29.72, 15.28, 15.02, 14.63, 12.72. HRMS (MALDI):  $m/z$  calcd for  $[C_{130}H_{70}B_2F_4N_{10}O_2]^+$ : 1900.5805; found 1900.5927,  $[M-F]^+$  1880.6173,  $[M-C_{60}]^+$  1181.6094.

**Compound B-5.** Under Ar, a mixture of **2** (58.1 mg, 0.1 mmol), phenylboronic acid (72 mg, 0.6 mmol) and  $K_2CO_3$  (41.7 mg, 0.3 mmol) was dissolved in toluene/ethanol/water (15 mL, 2/2/1, v/v), and the mixture was bubbled with Ar for 15 min.  $Pd(PPh_3)_4$  (18.1 mg, 0.015 mmol) was added. The mixture was refluxed for 3 h. After completion of the reaction, the mixture was cooled to RT, water (30 mL) was added, and the mixture was extracted with dichloromethane (3×50 mL). The organic layers were dried over  $Na_2SO_4$ . After removal of the solvent under reduced pressure, the mixture was purified by column chromatography (silica gel, DCM/petroleum = 1:1, v/v) to give deep purple solid. Yield: 47.8 mg (90 %).  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.55 (d, 3H,  $J$  = 8.4 Hz), 7.48 (d, 3H,  $J$  = 6.4 Hz), 7.30 (d, 1H,  $J$  = 8.0 Hz), 7.23 (d, 1H,  $J$  = 16.0 Hz), 7.16 (d, 2H,  $J$  = 7.6 Hz), 6.99 (s, 2H), 6.61 (s, 1H), 3.05 (s, 6H), 2.55 (s, 3H), 1.42 (s, 3H), 1.29 ppm (s, 3H).  $^{13}C$  NMR (100 MHz,  $CDCl_3$ ): 154.9, 151.7, 143.0, 139.3, 137.8, 135.7, 134.3, 133.5, 133.1, 131.0, 130.6, 130.4, 129.9, 129.4, 129.2, 129.0, 128.6, 128.4, 126.2, 118.0, 114.9, 112.5, 40.7, 29.9, 14.9, 12.7 ppm. HRMS (MALDI):  $m/z$  calcd for  $[C_{34}H_{32}BF_2N_3]^+$ : 531.2657; found 531.2694.

**Compound 10.** Under Ar, a mixture of **8** (41.0 mg, 0.10 mmol), **7** (66.7 mg, 0.10 mmol) were dissolved in  $CHCl_3/EtOH/H_2O$  (14 mL, 12/1/1, v/v),  $CuSO_4 \cdot 5H_2O$  (2.5 mg, 0.10 mmol) and sodium ascorbate (3.8 mg, 0.020 mmol) were added. The mixture was stirred at RT for 24 h. After completion of the reaction, the mixture was washed in water (3×20 mL). The organic layers were dried over  $Na_2SO_4$ . After removal of the solvent under reduced pressure, the mixture was purified by column chromatography (silica gel, DCM/methanol = 100/1, v/v) to give black solid. Yield: 93.9 mg (90 %).  $^1H$  NMR (400 MHz,  $CDCl_3$ ):  $\delta$  = 7.92 (s, 1H), 7.52–7.45 (m, 3H), 7.28 (s, 1H), 7.24 (s, 1H), 7.21–7.17 (m, 4H), 7.13 (d, 2H,  $J$  = 8.4 Hz), 7.00 (d, 2H,  $J$  = 8.0 Hz), 6.72 (d, 2H,  $J$  = 5.2 Hz), 6.64 (s, 1H), 5.97 (s, 2H), 5.27 (s, 2H), 4.85–4.83 (m, 2H), 4.47–4.44 (m, 2H), 3.04 (s, 6H), 2.65 (s, 3H), 2.55 (s, 6H), 1.42 (s, 9H), 1.40 ppm (s, 3H). HRMS (MALDI):  $m/z$  calcd for  $[C_{52}H_{51}B_2F_4N_8O_2]^+$ : 1044.3302; found 1044.3279.

### Nanosecond time-resolved transient difference absorption spectroscopy

Nanosecond time-resolved transient difference absorption spectra were recorded on a LP 920 laser flash photolysis spectrometer (Edinburgh Instruments, Livingston, UK). The sample solutions were purged with  $N_2$  for 20 min before measurements were taken. The samples were excited with 532 nm nanosecond pulsed laser and the transient signals were recorded on a Tektronix TDS 3012B oscilloscope.

### Cyclic voltammetry

Cyclic voltammetry was performed using a CHI610D Electrochemical workstation (Shanghai, China). Cyclic voltammograms were recorded at scan rates of 100 mV/s. The electrolytic cell used was a three electrodes cell. Electrochemical measurements were performed at RT using 0.1 M tetrabutylammonium hexafluorophosphate (TBAP) as supporting electrolyte, after purging with  $N_2$ . The working electrode was a glassy carbon electrode, and the counter electrode was platinum electrode. A non aqueous  $Ag/AgNO_3$  (0.1 M in acetonitrile) reference electrode was contained in a separate compartment connected to the solution via semipermeable membrane.  $CH_3CN$  was used as the solvent. Ferrocene was added as the internal references.

## Graphical Abstract:

Switch the triplet excited state of the C<sub>60</sub>-dimethyl-aminostyryl bodipy dyads/triads

Ling Huang and Jianzhang Zhao\*

Switching of the triplet excited state of Bodipy-C<sub>60</sub> dyads/triads with acid/base was studied with nanosecond time-resolved transient difference absorption spectroscopy.
