Abstract: Chiral hexahydroquinolizinones 13 and tetrahydroindolizinones 17 were prepared from functionalized chiral dihydropyridines by regio- and diastereoselective sonochemical cyclization.

We have recently described an efficient asymmetric synthesis of chiral 1,4-dihydropyridines 1 by the addition of organocopper reagents to chiral aminal 2 in the presence of various acyl chlorides (Scheme 1).¹

The possibility of utilizing functionalized acyl chlorides was exploited in short syntheses of chiral indolo and benzoquinolizines 3 and 4, involving a cyclization on the C₅-C₆ double bond of the dihydropyridine ring (X in Scheme 2).¹

We now report that the use of chlorobutanoyl or chloropropanoyl chloride allows the preparation of functionalized 1,4-dihydropyridines which can be used for the synthesis of close precusors of chiral quinolizidines 5 and indolizidines 6,² via a cyclization involving the C₂-C₃ double bond (Y in Scheme 2).

Addition of ethyl or methyl copper on aminal 2 (prepared with a diamine of S,S configuration) in the presence of 4-chlorobutanoyl chloride (Scheme 3) afforded aminals 7 in good yield (91%) as unique diastereomers, as shown by ¹H NMR. An acidic hydrolysis afforded the chlorodihydropyridines 8 (of R configuration¹) which were then converted into iododihydropyridines 9.

By analogy with several reports on radical cyclizations of similar systems,³ the pure crude iododihydropyridines 9 were treated with Bu₃SnH and AIBN in benzene under reflux to give, after isolation by flash chromatography (SiO₂, ether), 10 and 11 resulting from a cyclization on the C₂-C₃ or C₅-C₆ double bond (10/11 = 2/1) and the reduction products 12 (Scheme 4).

The bicycles 10 were obtained as a mixture of diastereomers (9/1) as shown by ¹H NMR. In the presence

of sodium carbonate in methanol, 10 (Me) afforded 13⁴ in a very good diastereomeric purity (de>95%). Reduction of 13, according to Scheme 4, gave the quinolizidine 14⁵ as a crystalline compound. The relative configuration of the three stereogenic centers of 14 (fig.1), determined by X ray analysis, indicated that the radical obtained from 9 cyclized *cis* to the C₄ substituent. The two diastereomers 11 (de = 50%) were separated by preparative thin layer chromatograhy (SiO₂, ether, 2 migrations), and the relative configuration of the major diastereomer was determined by ¹H NMR (NOE effects, Scheme 5). These results indicated that again, the cyclization occured mainly *cis* to the C₄ substituent (Scheme 5).

After several unsuccessful attempts to increase the regioselectivity of the cyclization, we have employed the Luche conditions: sonication of 9 in isopropanol in the presence of Zn and CuI (Scheme 6).⁶ Under these conditions, a regioselective reaction was observed affording 10 (as a mixture of diastereomers) in 60% yield, the reduction product 12 (30%) and the "free" dihydropyridine 15 (10%).

As previously described in Scheme 4, the diastereomeric mixture 10 was quantitatively converted into the diastereomerically pure 13 under basic conditions. Therefore, the stereochemistry of the cyclization obtained under sonication is the same as the one observed with Bu₃SnH, AIBN.

A similar study was performed on the iododihydropyridine 16 prepared as for 9 (Scheme 3) using 3chloropropanoylchloride. With Bu₃SnH / AIBN, two regioisomers 17 (de >95%), 18 (de = 50%) and the reduction product 19 were obtained (Scheme 7). The relative configuration of 17 was determined by ¹H NMR (NOE effects) suggesting as before that again the cyclization occurs *cis* to the C4 substituent, but with epimerization of the aldehyde substituent *in situ*. Using Luche's conditions, only one regioisomer 17⁷ was obtained (50% yield, de >95%) with the by-products 19 (30%) and 15 (10%).

In conclusion, we have described regio- and diastereoselective cyclizations of functionalized dihydropyridines affording bicyclic compounds which are possible precursors of benzo and indoloquinolizines. Applications of this methodology are in progress.
