A NEIGHBOURING GROUP PARTICIPATION OF *ORTHO*-METHOXYL GROUP IN SOLVOLYTIC REACTION OF SPIRO[2.5]OCTA-1,4,7-TRIEN-6-ONES

Toshihiko IKEDA, Shinjiro KOBAYASHI, and Hiroshi TANIGUCHI Department of Applied Chemistry, Faculty of Engineering, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812

In aqueous ethanol l-aryl-5,7-di-t-butyl-2-(o-methoxyphenyl)spiro[2.5]octa-1,4,7-trien-6-one $\underline{4}$ changed to 2-aryl-3-(3',5'-di-tbutyl-4'-hydroxyphenyl)benzofuran $\underline{5}$ in a more than 90% yield. The selective formation of $\underline{5}$ is ascribed to a neighbouring group participation of the *ortho*-methoxyl group to an incipient vinyl cation.

There are many examples of neighbouring group participations which are one of the most interesting subjects in the chemistry of trivalent carbocations.¹⁾ However, there are only a few examples^{2,3)} in the chemistry of vinyl cations which have been well-established.⁴⁾ We reported exclusive formation of benzofuran derivatives without an anchimeric acceleration by the *ortho*-methoxyl group in the sol-volysis of vinyl bromide $\underline{1}$,⁵⁾ while we suggested a neighbouring group participation of the methoxyl group in the reaction of spiro[2.5]octatrienone $\underline{3}$ which was intervenient in the solvolysis of vinyl bromide $\underline{2}$.⁶⁾

We would like to report here evidence for a neighbouring group participation

of the *ortho*-methoxyl group in the solvolytic reaction of 1-aryl-5,7-di-t-butyl-2-(o-methoxyphenyl)spiro[2.5]octa-1,4,7-trien-6-one 4.⁷⁾

The reaction of spiro[2.5]octatrienone $\underline{4c}$ (0.17 mmol) in ethanol (10 ml) at ambient temperature for 36 h gave benzofuran $\underline{5c}$.⁸⁾ Similar treatments of $\underline{4a}$, $\underline{4b}$, and $\underline{4d}$ also gave $\underline{5a}$, $\underline{5b}$, and $\underline{5d}$, respectively, as shown in Table 1. In all cases benzofuran $\underline{5}$ was obtained in a more than 90% yield, while the solvent-incorporated products, the vinyl ethyl ethers and the ketones, could not be detected. Benzofuran $\underline{5}$ was formed by breaking the specific C-C bond of the cyclopropene ring(path a). However, under acidic conditions the reaction of $\underline{4c}$ gave not only $\underline{5c}$ but also a product through the other C-C bond cleavage(path b). For instance, the mixture of $\underline{4c}$ (0.3 mmol), ethanol (9 ml), and trifluoroacetic acid (1 ml) was kept to stand at a room temperature for 46 h, and after evaporation of the solvent with a water pump $\underline{5c}$ and ketone $\underline{6}^{8}$ were obtained in 86 and 14% yields, respectively.

To reveal the reaction mechanism for the selective formation of benzofuran 5 the reaction rates of 4 were measured and the obtained first-order rate constants are shown in Table 2 and 3. The reaction was accelerated by substitution of an electron donating group (MeO>Me>H>Br). The Hammett plots against σ^+ afforded a negative ρ^+ , -2.3. Furthermore, a rate enhancement was observed with increasing water content in the solution, and a Grunwald-Winstein's m-value, 0.45, was calculated. As shown in Table 3 the rate constants were unchanged in basic solutions but in more acidic solutions (pH <10.5) the rate increased as the pH decreased. The degree of these effects in a substituent, solvent polarity, and solvent's pH were lower than those in the solvolysis of spiro[2.5]octatrienone 7 to generate vinyl cation 8 (ρ^+ = -3.0, m= 0.53, and 670 time-faster rate in pH 9.75 than in pH

Compound	Solvent	5	(%) * <u>6</u>	(%) * ** (%) *
<u>4a</u>	97% EtOH-3% H ₂ O	100	0	0
<u>4b</u>	100% EtOH	98	0	2

15, respectively).⁹⁾ These phenomena are well explained by considering an anchimeric assistance of the *ortho*-methoxyl group in the formation of benzofuran <u>5</u>. Hydrogen bonding or protonation on the carbonyl oxygen perturbs the cyclopropene ring to weaken both C-C bonds of the ring. Judging from the results in the solvolysis of <u>7</u>, bond <u>b</u> must break more easily than bond <u>a</u> to give more stable vinyl cation in cases of <u>4b-d</u>. However, the cleavage of bond <u>a</u> occures faster than that of bond <u>b</u>. The cleavage of bond <u>a</u> should be caused by an intramolecular nucleophilic attack of the *ortho*-methoxyl group, that is, a neighbouring group participation. This mechanism is also consistent with the following results; i) the relative rate of <u>4c</u> to <u>7c</u>, both of which are considered to generate α -phenylvinyl cations, was 336 and ii) the extent of cleavage of bond <u>a</u> to bond <u>b</u> was larger in a basic solution than in an acidic solution, because the neighbouring group participation should depend on the perturbation of the bond <u>a</u>, that is, the neighbouring group participation must be more effective in case of hydrogen bonding (in a basic solution) than in case of protonation.

Table 2 Kinetics of 1-ary1-5,7-di-t-buty1-2-pheny1- and 5,7-di-t-buty1-1,2-dipheny1spiro[2.5]octa-1,4,7-trien-6-ones in aqeous ethano1
