

Coordination Chemistry and Photoreactivity of the Dinitramide Ion

Scott Trammell, Patricia A. Goodson, and B. Patrick Sullivan*

Department of Chemistry, University of Wyoming, Laramie, Wyoming 82071-3838

Received October 18, 1995

The dinitramide ion (N_3O_4^-) is a relatively new simple nitrogen oxyanion of theoretical¹ and practical interest.² Despite its potential as a non-chlorine containing, high energy density material, its chemistry is not well understood.³ Such studies are of importance since possible environmental effects of N_3O_4^- include its ability to act as a potent oxidant and/or nitrating agent.⁴ From a published description of X-ray structural studies of several dinitramide salts,⁵ it is apparent that N_3O_4^- can act as a ligand to transition metals.⁶ For example, three of the possible coordination modes to a single metal are depicted by structures I–III where only the skeletal atoms are shown, and M represents a transition metal complex fragment. It should be noted that structures I and III are similar to bonding modes known for the acetylacetonate ion. Prediction of the dominant bonding mode of N_3O_4^- should be facilitated by knowledge of the site of protonation in dinitramine acid (HN_3O_4); unfortunately this is the subject of debate with structures analogous to I and III being suggested.^{1a,f,2b,d,h,3d}

Here we report the first demonstrated metal complex of N_3O_4^- , the first published X-ray structure of the coordinated ion, and an unusual example of an intramolecular photosensitized reaction of a coordinated ligand (N_3O_4^-) via a metal-to-ligand charge transfer excited state.

Reaction of KN_3O_4 with the reactive precursor *fac*-Re(bpy)-(CO)₃OSO₂CF₃ at room temperature in water gives a yellow microcrystalline solid which when recrystallized slowly from hexanes/CH₂Cl₂ gives thin yellow plates of *fac*-Re(bpy)-(CO)₃N₃O₄ in 75% yield.⁷ The replacement of triflate by dinitramide is suggested by their relative acidity i.e., –14.6⁸ versus –5.6,^{1b} respectively.

The X-ray crystal structure^{9a} (Figure 1) of *fac*-Re(bpy)-(CO)₃N₃O₄ clearly shows that coordination occurs at the central nitrogen of the dinitramide skeleton with the rest of the complex possessing the typical facial geometry exhibited by Re(bpy)-(CO)₃X complexes. The Re–N bond lengths for the bpy ligand are 2.166(10) Å (Re(1)–N(4)) and 2.160(10) Å (Re(1)–N(5)). The Re–bpy bond lengths are typical of those in similar complexes of the type *fac*-Re(bpy)(CO)₃X (for X = OSO₂CF₃^{9c} and PO₂F₂^{9d} bond lengths are between 2.140 and 2.150 Å). The Re–N₃O₄ (Re(1)–N(2)) bond length is considerably longer, 2.223(10) Å, consistent with its being a weaker donor than pyridine type ligands. A structurally interesting feature is the “tilting” of the planar nitro groups away from each other along the Re(1)–N(2) axis.

fac-Re(bpy)(CO)₃N₃O₄ is extremely photosensitive in solution. This is demonstrated in Figure 2 where changes in the UV–visible spectrum in CH₂Cl₂ (2.57 × 10^{–5} M) after irradiation (436 nm, 1000 W Hg lamp in a one cm cuvette) demonstrate the formation of a new product. Analysis¹⁰ of the spectral changes (436 nm irradiation; monitoring the spectrum between 230 and 550 nm) is best approximated as an A → B → C process (see inset in Figure 2). Preparative photolysis in CH₂Cl₂ allows the isolation and characterization of C, which is

- (7) Synthesis of *fac*-Re(bpy)(CO)₃N₃O₄. *Caution!* Dinitramide derivatives are known to be shock sensitive and explosive.^{3a} In 20 mL of deionized water, 0.1 mmol (57 mg) of Re(bpy)(CO)₃OSO₂CF₃ was heated to reflux until dissolved in a 100 mL round bottom flask. After the solution was allowed to cool to room temperature, 1.0 mmol (0.145 mg) of KN(NO₂)₂ was added and the solution was stirred overnight in the dark. A yellow microcrystalline solid was collected by vacuum filtration and washed with 3 × 15 mL of water and then allowed to air dry. Crystals were grown for X-ray diffraction and elemental analysis by slow diffusion of hexanes into a concentrated solution of product in CH₂Cl₂. Anal. Calcd for ReC₁₃H₈N₅O₇: C, 29.33; H, 1.51; N, 13.15. Found: C, 29.53; H, 1.59; N, 12.88. ¹H NMR (δ/ppm, CDCl₃): 9.15 (m, 2H), 8.18 (m, 4H), 7.62 (m, 2H). ¹H NMR (δ/ppm, CD₂Cl₂): 9.02 (m, 2H), 8.14 (m, 2H), 8.08 (m, 2H), 7.55 (m, 2H). UV–visible (λ (nm), CH₂Cl₂) (ε in M^{–1} cm^{–1}): 246 (19 100), 266 (16 650), 320 (10 700), 370 (3650). IR (CHCl₃) (ν (CO) cm^{–1}): 2036, 1940, 1924. IR (CH₂Cl₂) (ν(CO) cm^{–1}): 2036, 1934, 1925.

Figure 1. X-ray crystal structure of *fac*-Re(bpy)(CO)₃N₃O₄.

Figure 2. UV-visible spectra of (a) *fac*-Re(bpy)(CO)₃N₃O₄ (A), (b) the intermediate complex (B) formed during photolysis and, (c) *fac*-Re(bpy)(CO)₃NO₃ plus the minor product (C) (as determined by global analysis of the kinetic process; 2.57×10^{-5} M in CH₂Cl₂).

identified as the nitrate complex *fac*-Re(bpy)(CO)₃NO₃. We also observe a minor product which tentatively has been assigned as the chloro complex *fac*-Re(bpy)(CO)₃Cl. Independent verification of the nitrate complex is provided by the preparation of this new complex by reaction of *fac*-Re(bpy)(CO)₃OSO₂CF₃ with NaNO₃ in water.¹¹ The stoichiometry of the photolysis was determined by IR and NMR spectroscopic studies of the course of the reaction. After complete consumption of *fac*-Re(bpy)(CO)₃N₃O₄, the product distribution (with respect to the metal) is 90% *fac*-Re(bpy)(CO)₃NO₃. N₂O¹² is

also produced, which is consistent with the reaction written in eq 1. The mechanism of formation of the minor product is not

yet understood and the fate of NO₃[−] in the minor pathway has yet to be determined. N₂O and NO₃[−] have been identified as the dominate photochemical decomposition products of N₃O₄[−], in aqueous solution.^{2j}

The photoreaction in eq 1 is extraordinary. Since irradiation at 436 nm predominantly populates Re(I) to bpy MLCT excited states to the exclusion of dinitramide states ($\phi_{366} = 0.061$ for KN₃O₄ in water), it is apparently a rare example^{13,16} of intramolecular chemistry photosensitized by a MLCT excited state. This is made more intriguing by the fact that the quantum yield (ϕ_{436}) is 0.67 ± 0.05 ¹⁴ (determined with the ferrioxalate actinometer in air saturated H₂O).¹⁵ Our current studies are concentrated on further defining the coordination chemistry and photochemistry of this new ligand.¹⁶

Acknowledgment. B.P.S. thanks the AFOSR for funding (Grant 93-NC-193), and we thank Dr. Robert J. Schmitt (SRI International) for providing the sample of KN₃O₄ that made this work possible.

Supporting Information Available: For *fac*-Re(bpy)(CO)₃N₃O₄, tables of atomic coordinates and isotropic displacement coefficients (Table 1), bond lengths (Table 2), bond angles (Table 3), anisotropic displacement coefficients (Table 4), hydrogen coordinates and isotropic displacement coefficients (Table 5), crystallographic data collection parameters (Table 6), and solution and refinement parameters (Table 7) (7 pages). Ordering information is given on any current masthead page.

- (9) (a) Single-crystal X-ray data were collected at 23 °C using a yellow crystal of dimensions $0.45 \times 0.20 \times 0.02$ mm on a Siemens P3 diffractometer equipped with a molybdenum tube [$\lambda(\text{K}\alpha_1) = 0.70926$ Å; $\lambda(\text{K}\alpha_2) = 0.71354$ Å] and a graphite monochromator. The compound crystallized in the centrosymmetric triclinic space group P1 with two molecules in a cell of dimensions $a = 8.035(2)$ Å, $b = 8.161(2)$ Å, $c = 12.365(2)$ Å, $\alpha = 97.36(3)^\circ$, $\beta = 101.24(3)^\circ$, $\gamma = 91.66(3)^\circ$, and $V = 787.6(3)$ Å³. A total of 3091 independent reflections were gathered ($R_{\text{int}} = 0.023$), the octants collected being $\pm h, \pm k, \pm l$, using the Wyckoff scan method. Three standard reflections were measured after every 100 reflections collected. The structure was solved by direct methods and refined by full-matrix least-squares techniques using structure solution programs from the SHELXTL system.^{9b} All nonhydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions (C–H = 0.96 Å) and refined with fixed isotropic thermal parameters. The structure has been refined to conventional R factor values of $R = 0.0478$ and $R_w = 0.0582$ on the basis of 2448 observed reflections with $F < 6\sigma(F)$ in the 2θ range $4\text{--}52^\circ$ ($R = 0.0627$, $R_w = 0.0617$ for all data), giving a data to parameter ratio of 10.4:1. The maximum and minimum residual densities remaining were $+2.91$ and -3.06 e Å^{−3}, respectively, and located near Re(1). The data were corrected for absorption using semiempirical techniques. - (16) Electrochemical studies of N₃O₄[−] in H₂O⁶ show a series of reductive processes in the range of -0.3 to -0.82 V (vs Ag/AgCl) that give rise to nitrite but not nitrate. No oxidative processes are observed to the solvent limit (ca. +1.2 V). Given this, it is very unlikely that intramolecular reductive quenching can occur in the Re(I) complex with a significant rate. Thus, the mechanism could be intramolecular oxidative quenching that yields a coordinated but reduced N₃O₄[−] that fragments in a different fashion than direct electrochemical reduction at an electrode (back electron transfer would then be required to reduce Re(II) to Re(I) via a product of N₃O₄[−] decomposition). Alternatively, the mechanism could be energy transfer sensitization which gives the same state that is responsible for photodecomposition of free dinitramide ion.^{2j}
