Abstract: Employing an intramolecular Michael addition as a pivotal step, butenolide 5, furans 6 and 7 have been converted to dioxaspiro compounds 8, 9, 10 and 11, whose heterocyclic frameworks constitute important structural units of prehispanolone (2) as well as 14,15-dihydroprehispanolones (3) and (4), respectively. Hispanolone (1) was converted to 2, 3 and 4 by utilizing a similar strategy. Copyright © 1996 Elsevier Science Ltd

Hispanolone (1) was obtained from *Ballota hispanica* for the first time in 1978.³ The transformation of 1 into its 8 β -acetoxy counterpart, galeopsin, has been reported, together with its retro-aldol reaction in addition to other B ring transformations.⁴ Preparation of drimane derivatives by using 1 as a precursor have also been reported.⁵ The conversions of 1 to a perfumery substance, ambreinolide and to drimane sesquiterpenoids have also been described recently.⁶ We recently reported the identification of labdane diterpene, namely prehispanolone (2) from the aerial parts of *Leonurus heterophyllus* (Yi Mu Cao).^{1d} It was found that 2 can be converted readily to 1 by mild acid treatment,^{1d,7} and indeed 1 become the sole product if neutral condition was not rigorously maintained during the isolation. Using an *in vitro* radioligand binding assay for the platelet activating factor (PAF) receptor,⁸ compound 2 was identified as a specific PAF receptor antagonist.^{1c} In remarkable contrast, 1, which has been deprived of the tetrahydrofuran ring, did not interact with the PAF receptor.^{1c} Catalytic hydrogenation of 2 converted it to the bioactive and acid-insensitive 14,15-dihydroprehispanolone (3).^{1c,1d} Interestingly, in addition to being more acid-resistant than 2, compound 3 was a much better ligand for PAF receptor.^{1c} For further pharmacological evaluation purpose, it appears that both 2 and 3 are good leads for a structure-activity relationship study.

In view of the structural simplicity as well as the ready availability of 1, as compared with those of 2 and 3, we reason that 1 can serve as a pivotal intermediate *en route* to the total synthesis of 2 and 3. In order to assess such possibility, we also initiated a synthetic program with the aim to construct several model compounds, namely 5, 6, 7, 8, 9, 10 and 11. As can be seen, compounds 6 and 7 contain the functional characteristics of those of 1, so they are able to allow the substantiation of our aforementioned argument.

Butenolide 5, on the other hand, serves as an anchor molecule for our key intramolecular Michael cyclization step (*vide infra*), leading eventually to 8. While 6 would be the precursor of 9, we thought that the possible lower-boiling properties of 8 and 9 would cause a minor work-up problem. In this connection, we have also prepared the diphenyl analog 7 for the realization of 10 and 11.

Synthesis of Model Compounds

To our best knowledge, no arduous attempt to construct dioxaspiro[4.4]nonane framework⁹ similar to that of 2, 3 and 4 has been reported, notwithstanding that such spiro moiety is a common structural unit in many natural products.^{7,10} Our preliminary strategy employed for the synthesis of 8 was based on the intramolecular Michael addition of 5. In order to examine the feasibility of this reaction, we elaborated a shorter route to synthesize the model molecule 8 from commercially available 3,3-dimethylacrylic acid (12) (Scheme 2).

As outlined in Scheme 2, the synthesis of 5 from 12 was straightforward.¹¹⁻¹⁴ An intramolecular Michael addition of 5 gave 17 as a mixture of diastereomers.¹⁵ The structure of the diastereomeric lactone 17 was confirmed by examining the ¹H NMR (Table 1) and ¹³C NMR (Table 2) spectra of one of its diastereomers, as well as by its IR, MS and elemental analysis (see Experimental Section). Finally, 17 was converted¹⁶ via the diastereomeric 18 to give 8 also as a diastereomeric mixture. As expected, the ¹H NMR spectrum of 8 showed the characteristic upfield shift for H-8 (δ 3.90) of 8 as compared with H-8 (δ 5.45) of the corresponding lactol 18. Tables 3 and 4 summarize the assignments of the proton and C-13 absorptions of spiroethers 8, 9, 10 and 11, respectively (assignments of only one diastereomer are shown in the case of diastereomeric mixtures).

Despite the successful synthesis of spiroether 8, the route shown in Scheme 2 is not suitable for natural 1. In our particular case, we were guided by the desire to develop a method which would deliver a butenolide moiety from a furan functionality, thereby facilitating the realization of 2 directly from 1.

Our synthetic pathway therefore called for the direct introduction of the trimethylsilyl group to C-15 position of hispanolone (1) in a regioselective manner. If this regioselective method indeed works, our strategy would provide a convenient new pathway to the spiroether diterpenes. In order to examine the feasibility of such strategy, we elaborated a route to synthesize the model molecule **8** from commercially available 3-furancarboxylic acid (19). As shown in Scheme 3, regiospecific bromination of 19 provided the corresponding 5-bromo-3-furoic acid **20**.¹⁷ Metal-halogen exchange and silylation of the dianion derived from **20** gave **21**.¹⁸ Reduction and bromination of acid **21** afforded the desired bromomethyl furan **23**.¹⁹ Alkylation of ethyl acetoacetate with **23** provided furyl ester **24** in 85% yield.¹² Finally, peracetic acid oxidation of ester **24** gave butenolide **15**.²⁰ Again, a similar transformation of butenolide **15** generated the model compound **8** via **16**, **5**, **17** and **18**, as illustrated in Scheme 2

In order to test the possibility of executing an intramolecular Michael addition for the tertiary hydroxy group-containing lactone 40, we synthesized spiroether 9 from the commercially available 3-furancarboxylic acid (19) (Scheme 4). All attempts to convert the butenolide 16 (see Scheme 2) to lactone 40 using methyllithium were unsuccessful. This was mainly due to the chemoselectivity problem involving the ketone and the α,β -unsaturated lactone. In light of this fact, we decided to modify our previous strategy for the realization of the model compound 9. The ultimate synthetic route for 9 is depicted in Scheme 4. The synthesis of furan 29 from acid 19 was straightforward.¹² Addition of methyllithium to 29 gave the desired hydroxyfuran $6.^{21}$ The deprotonation-silvlation of 6^{22} on the other hand, gave an inseparable mixture of 31 and 33, whose yields were determined by NMR spectrometry, together with a smaller amount of the isolable 35. Fortunately, peracid oxidation 20 of a mixture of 31 and 33 afforded a chromatographically separable mixture of 36 and 38. Desilvlation of 36 furnished 40.23 An intramolecular Michael addition of 40 was triggered by potassium carbonate, furnishing 42.¹⁵ The structure of lactone 42 was confirmed by its ¹H NMR (Table 1) and ¹³C NMR (Table 2) spectrometric studies, as well as by its MS and elemental analysis. Finally, the construction of the desired spiroether 9 was accomplished by reduction¹⁶ of 42 to 44, whose hydroxyl group was removed by silane reduction.¹⁶ Comparison of the ¹H NMR (Table 3) and ¹³C NMR (Table 4) data of 9 with 8 substantiated the structure of 9.

Encouraged by the above results, we thus set forth to extend our strategy for the conversion of lactol 44 to an unsaturated spiroether. In order to generate an unsaturated ether, lactol 44 was treated with 3 equivalents of MeSO₂Cl and 3.5 equivalents of pyridine in dichloromethane at room temperature.²⁴ Dehydration of lactol 44 directly to the enol ether using this method was however unfruitful. Ley and coworkers also reported an unsuccessful example of this direct dehydration in their synthesis of a model compound related to azadirachtin.²⁵ The above unsatisfactory outcome probably resulted from the instability of the unsaturated

spiroether in acidic condition. On the other hand, the low boiling point of the unsaturated spiroether might also cause considerable difficulties in its handling. Based on aforementioned consideration, we therefore attempted to replace the methyl groups of lactol 44 with phenyl groups. Again, a similar transformation of 3-furancarboxylic acid (19) generated spiroether 10, via alcohol 25, bromide 26, ester 28, ketone 30, alcohol 7, 2-trimethylsilyl substituted furan 32 and 34, butenolide 37, hydroxybutenolide 41, spirolactone 43 and lactol 45. Subsequent oxidation and elimination²⁵ of phenylsulfide 46 prepared from 45 eventually yielded 11. The structure of 11 was confirmed by its ¹H NMR (Table 3) and ¹³C NMR (Table 4) spectral data, as well as by its MS and elemental analysis. ¹H NMR spectra of 47 and 11 indicated the conversion of the phenylsulfinyl group of 47 into the double bond of 11 (δ 6.55, J = 2.6 Hz, and δ 5.09, J = 2.6 Hz for H-8 and δ 5.09, J = 2.6 Hz for H-9 of 11 versus δ 4.65-4.72 for H-8 and δ 2.10-2.20 and δ 3.05-3.15, J = 4.1, 7.4 Hz for two H-9 of 47). On the other hand, the ¹³C signals for C-8 and C-9 of 11 were shifted downfield to δ 149.1 and δ 106.2, respectively relative to those of the saturated spiroether 10 (δ 77.5 for C-8 and δ 34.9 for C-9).

Synthesis of Natural Products

Having secured a reliable approach to realize both spirotetrahydrofuran 8, 9 as well as 10 and spirodihydrofuran 11, similar routes were then utilized to construct natural products 2, 3 and 4 from the readily available 1.^{1d} As shown in Scheme 5, protection of the keto group of 1 gave 48. As anticipated, deprotonation and silylation of 48 yielded a mixture of 49 and 50, which was not separated and was oxidized with peracid to furnish a chromatographically separable mixture of butenolides 51 and 52. Desilylation of 51 converted it to the key intermediate 53, which underwent an intramolecular Michael addition²⁶ to give again a chromatographically separable mixture of a pair of diastereomers 54 and 55, the only stereochemical difference being the 13S or 13R configuration, respectively. Unlike the intramolecular Michael cyclization of 5, 40 and 41, It is noteworthy that a similar reaction of 53 utilizing potassium carbonate¹⁵ led only to an inferior yield of 54 and 55. On the other hand, treatment of 5 and 40 with DBN-Et₃N²⁶ did not provide better yields of the lower-boiling 17 and 42 respectively due to the work-up difficulty in removing completely the higher boiling bases. It is significant to note that the biosynthetic pathway leading to the absolute configuration of the spiro carbon (C-13) in 2 is probably also non-enantiospecific, because two related compounds, namely scutellone B and scutellone G have been isolated and identified.²⁷

The 13S configuration of 54 was established by X-ray crystallographic analysis of 57 which was a side product of the DIBAL reduction of 54. The X-ray crystallographic analysis of 57^{1a} unequivocally certified its 13S configuration. Further conversion (deprotection and silane reduction) of 56 led to the "non-natural" 4, whose spiro carbon C-13 must be also of S configuration.

In principle, the verification of the 13S configuration of 54 also indirectly confirmed the 13R configuration of 55, which was likewise reduced to 58. Compound 3 was obtained upon silane reduction and concomitant deprotection of the ketal group, presumably due to the Lewis acid condition. The physical and spectroscopic properties of 3 were identical with those of a "natural" 3 obtained through catalytic hydrogenation of the natural 2.^{1d} However, it was necessary to apply a modified Ley procedure²⁵ to convert 58 to 2, presumbly due to the interference of the C-7 keto group regenerated during the conversion of 58 to 59. Thermal elimination of 61 eventually gave 2, whose physical and spectral data were identical to those of the natural 2.^{1d}

To conclude, we have devised a general synthetic strategy, by which both 2 and 3, as well as their respective (13S)-diastereomer 4 could be obtained from a common key intermediate 1. In order to complete the total synthesis of 2, an enantiospecific synthesis of the likely less synthetically demanding 49 is in

progress. Moreover, the diastereoselective Michael cyclization of 53 to either 54 or 55 is also under active investigation.

NMR spectra were recorded on a Bruker Cryospec WM 250 spectrometer. ¹H NMR (250.13 MHz) chemical shifts are reported relative to CDCl₃ at δ 7.24 ppm and Me₄Si at δ 0.00 ppm. Coupling parameters are reported in Hz. ¹³C NMR (62.89 MHz) chemical shifts are expressed relative to CDCl₃ at δ 77.00 ppm and Me₄Si at δ 0.00 ppm. NMR spectral terms are reported according to the following abbreviations: s, singlet; d, doublet; t, triplet; m, multiplet; dd, doublet of doublets. Mass spectra (EIMS and HRMS, VG Micromass 7070F spectrometer) were determined at an ionizing voltage 70 eV, relevant data were tabulated as *m/z*. IR spectra were run on a JASCO A-100 infrared spectrophotometer. Elemental analyses were performed at Shanghai Institute of Organic Chemistry, The Chinese Academy of Sciences, China.

(13R)-15-Phenylsulfinyl-9 α ,13;15,16-diepoxy-8 α -labdan-7-one (61)³¹

To a solution of **59** (15 mg, 0.04 mmol) in MeOH (2 mL) at 0°C was added a solution of 0.5 M NalO₄ (78 μ L, 0.04 mmol). After the mixture was stirred at 0°C for 5h, the precipitated NaIO₃ was removed by filtration, and the filtrate was diluted with CHCl₃ (40 mL). The organic layer was washed with 5% NaHCO₃ (2x10 mL) and brine (3x10 mL). Concentration under reduced pressure and chromatography of the residue on silica gel (elution with hexanes-ethyl acetate, 5:1) afforded 10.5 mg (67%) of **61** as a colorless oil: Compound **61** was used immediately in the next step without further purification and characterization.
