A Series of Rhodium(I) Complexes, including Carbene, Vinylidene and Allenylidene Derivatives, with the Bifunctional Arsine Pri2AsCH2CH2OMe as Ligand†

Peter Schwab and Helmut Werner*

Institut für Anorganische Chemie der Universtität Würzburg, Am Hubland, D-97074 Würzburg, Germany

A series of rhodium(I) complexes containing the new bifunctional arsine ligand Pri₂AsCH₂CH₂OMe I has been prepared. Most of the compounds were obtained from the ethene derivative trans- $\{RhCl(C_2H_4)(Pr_2AsCH_2CH_2OMe)_2\}$ 5 which was obtained from $[\{RhCl(C_2H_4)_2\}_2]$ and I in about 80% yield. The ethene can be displaced by CO, CNBut, CH₂=CHC(O)Me, CH₂=CHCO₂Me, HC=CPh, $HC = CCO_2Me$, $PhC = CSiMe_3$, MeC = CMe, PhC = CMe, MeC = CC = CMe or $Me_3SiC = CC = CSiMe_3$ (L) to give the four-co-ordinated rhodium(I) complexes trans-[RhCl(L)(Pri2AsCH2CH2OMe)2] almost quantitatively. The reaction of **5** with H₂ affords the dihydride $\{RhH_2Cl(Pr_2AsCH_2CH_2OMe)_2\}$ which appears to be fluxional in solution. Photolysis of 5 leads to the elimination of CH₂=CHOMe and the formation of trans-[RhCl(C₂H₄)(HAsPr'₂)₂] which is also accessible from 3 and HAsPr'₂. The vinylidene complexes trans-[RhCl(=C=CHR)(Pr₂AsCH₂CH₂OMe)₂] are obtained either on photochemically induced rearrangement of the isomeric alk-1-yne derivatives (R = Ph or CO2Me) or directly from 5 and HC=CR (R = Me or Bu¹). The reaction of 5 with a large excess of HC≡CMe or MeC≡CBu¹ gives the rhodium(I) allenes trans-[RhCI(CH₂=C=CHR)(Prⁱ₂AsCH₂CH₂OMe)₂] (R = H or Bu^t). The allenylidene compounds trans- $[RhCl(=C=C=CRR')(Pr'_2AsCH_2CH_2OMe)_2] \quad (R=Ph, R'=Ph \text{ or } C_6H_4Me-o) \text{ are obtained from the functionalized vinylidene derivatives } trans-[RhCl(=C=CHCRR'OH)(Pr'_2AsCH_2CH_2OMe)_2] \text{ upon treat-properties}$ ment with Al_2O_3 . From trans-[RhCl(=C=C=CRR')(Pr_2^i AsCH₂CH₂OMe)₂] and NaC_5H_5 the half-sandwiches [C₅H₅Rh(=C=C=CRR')(Pr'₂AsCH₂CH₂OMe)] have been prepared. Compound 5 reacts with N₂CPh₂ and $N_2C(C_6H_4Me-p)_2$ to yield the carbene complexes trans-[RhCl(=CR₂)(Pr₂,AsCH₂CH₂OMe),] whereas from 5 and N2CRC(O)Ph (R = H or Ph) the diazoalkane rhodium compounds trans-[RhCl{N,CRC(O)Ph}(Pr,AsCH,CH,OMe),] are obtained.

Our recent interest in the chemistry of transition-metal (Rh,² Ir,³ Ru,⁴ Os⁵) complexes containing various phosphinoethers as ligands,² 5 has prompted us to find out whether arsinoethers have similar co-ordinating properties. As has already been shown by Jeffrey and Rauchfuss,⁶ Braunstein and co-workers,⊓ Lindner and Bader® and others, phosphine derivatives of the general type R₂P(CH₂),nY (Y = OMe, NMe₂, CO₂Me, etc.) behave as hemilabile chelating ligands and, with the support of the weak M-Y bond, are able temporarily to protect a vacant co-ordination site. After cleavage of the M-Y bond, a reactive substrate (e.g., H₂, CO, C₂H₄, C₂H₂, etc.) can enter into the co-ordination sphere and, with the metal-ligand moiety acting as a template, may be transformed into a new product. It is therefore not surprising that several complexes with bifunctional phosphines R₂P(CH₂),nY as ligands are catalytically active species.

Since in our work with phosphinoethers, the compound Prⁱ₂PCH₂CH₂OMe has proved to be the most versatile ligand in stabilizing d⁶ and d⁸ metal centres, we attempted to prepare the corresponding arsine Prⁱ₂AsCH₂CH₂OMe by an analogous route. This paper describes the synthesis of the new ligand as well as that of a series of rhodium(1) complexes [RhCl(L)-(Prⁱ₂AsCH₂CH₂OMe)₂] including those in which L is a carbene, vinylidene or allenylidene unit.

Results and Discussion

Preparation of the Arsinoether.—Since Pri₂PCH₂CH₂OMe is accessible from HPPri₂,^{2a} the dialkylarsane HAsPri₂ (which is prepared from Pri₂AsCl and LiAlH₄⁹) has been used as

† Vinylidene Transition-metal Complexes. Part 33.1

Non-SI unit employed: Torr ≈ 133 Pa.

starting material for the synthesis of Prⁱ₂AsCH₂CH₂OMe I. Metallation of HAsPrⁱ₂ with LiBuⁿ yields the lithiated derivative LiAsPrⁱ₂ which reacts with ClCH₂CH₂OMe *in situ* to give I in about 70–75% yield [equation (1)]. At room

$$HAsPr_{2}^{i} \xrightarrow{(i) LiBu^{n}} Pr_{2}^{i}AsCH_{2}CH_{2}OMe \quad (1)$$

temperature, the arsinoether is a colourless, extremely airsensitive liquid which is soluble in all common organic solvents. Due to its sensitivity the adduct of I with methyl iodide instead of the free arsine has been characterized by elemental analysis. The ¹H NMR spectrum of I displays, besides the singlet for the OCH₃ hydrogens, two doublets for the protons of the diastereotopic methyl groups of the isopropyl units. one septet for the two equivalent AsCH protons and two unresolved multiplets for the hydrogen nuclei of the CH₂CH₂ bridge. The inequivalence of the methyl groups is also illustrated by the ¹³C NMR spectrum in which two signals are observed for the AsCH*C*H₃ carbons.

Carbonyl, Isocyanide, Hydrido and Olefin Complexes with $[RhCl(Pr_2^iAsCH_2CH_2OMe)_2]$ as Molecular Unit.—The bis-(cyclooctene)rhodium(i) compound $[\{RhCl(C_8H_{14})_2\}_2]$ 1, which on treatment with $Pr_2^iPCH_2CH_2OMe$ affords the monomeric substitution product $[RhCl(Pr_2^iPCH_2CH_2OMe)_2]$, 2a unexpectedly reacts with I to give the dimeric complex 2 (see Scheme 1). Even an excess of the arsinoether leads to the same result. In contrast, the course of the reaction of the bis(ethene)rhodium(I) compound $[\{RhCl(C_2H_4)_2\}_2]$ 3 with I is strongly dependent on the amount of the arsinoether added. Whereas from 3 and two equivalents of I, the chloro-bridged

dimer 4 is formed in excellent yield, only the monomeric product 5 is obtained on reaction with four equivalents (or an excess) of I. The obvious assumption that 4 is an intermediate in the formation of 5 has been substantiated by treatment of 4 with 2-3 equivalents of I which gives the bis(arsinoether) complex almost quantitatively. The three products, 2, 4 and 5, are orange to orange-yellow crystalline solids for which correct elemental analyses have been obtained. The ¹H NMR spectrum of complex 5 which displays two doublets for the AsCHCH₃ protons leaves no doubt that the arsine ligands are in trans

On treatment of compound 5 with CO, CNBu^t or H₂, the ethene is readily displaced and complexes 6-8 are formed in nearly quantitative yield. The carbonyl compound 6 shows a CO stretching frequency at 1974 cm⁻¹ which is similar to that of trans-[RhCl(CO)(AsPri₃)₂]. 10 In contrast to 6 and 7 which are yellow, moderately air-stable solids, the dihydride 8 is an orange-red air-sensitive oil. At 25 °C, the ¹H NMR spectrum displays only one signal for the hydride ligands at δ ca. -23, while at low temperatures two resonances (both doublets of doublets) at $\delta-13.4$ and -22.2 are observed. We therefore assume that a rapid equilibrium between two enantiomeric octahedral (A, C) and one short-lived five-co-ordinate species (B) exists at room temperature [see equation (2)] which below -30 °C is frozen out giving a spectral pattern of a species containing two inequivalent arsinoether ligands. We note that

for the related phosphinoether rhodium complex [RhH₂Cl-(Pr₂PCH₂CH₂OMe)₂] only one hydride resonance and one signal for each of the PCHCH₃ and OCH₃ protons is observed even at -80 °C.^{2a} Furthermore, it is worth mentioning that in the reaction of 5 with H2 ethane is formed and that on treatment of 8 with C_2H_4 the olefin complex 5 is regenerated.

During attempts to transform compound 5 to the isomeric hydrido(vinyl)rhodium(III) species [RhH(CH=CH₂)Cl(Pri₂-AsCH₂CH₂OMe)₂], an unexpected observation has been made. Instead of an intramolecular C-H activation of the olefinic ligand, as occurs on irradiation of *trans*-[IrCl(C₂H₄)-(Prⁱ₂PCH₂CH₂OMe)₂],^{3a} the photolysis of **5** in benzene solution leads to the elimination of methyl vinyl ether and the formation of the bis(diisopropylarsine)rhodium(I) complex 9 (see Scheme 2). Since it has been proved by an independent experiment that under the same conditions the free arsinoether I does not react to give HAsPri2 and CH2=CHOMe, there is no doubt that the fragmentation of 5 is a rhodium-assisted process. Compound 9, which is more conveniently prepared from 3 and four equivalents of HAsPri2, is an orange-yellow crystalline solid that has been fully characterized by elemental analysis and spectroscopic means.

The ethene ligand in 5 cannot only be displaced by CO, CNBut and H₂ but also by substituted olefins (Scheme 2). The use of methyl vinyl ketone and methyl acrylate as olefinic substrates was initiated by our recent finding 11.12 that both

 $[\{RhCl(PPr^{i}_{3})_{2}\}_{n}]$ and $[IrCl(C_{8}H_{14})(PPr^{i}_{3})_{2}]$ react with $CH_{2}=$ CHR [R = C(O)Me or CO₂Me] to give via π -co-ordination and subsequent C-H activation the octahedral rhodium(III) and iridium(III) derivatives [MH{CH=CHC(R)=O}Cl(PPrⁱ₃)₂] (M = Rh or Ir). However, the arsinoether complexes 10 and 11, which are prepared from 5 and CH₂=CHR in pentane at room temperature, are thermally as well as photochemically quite inert. Even after prolonged heating of 10 or 11 in benzene solution to 70 °C no further rearrangement occurs. As in the ¹H and ¹³C NMR spectra of complex 11 at room temperature two signals for the AsCHCH₃ protons and the AsCHCH₃ carbon atoms are observed, we conclude that the rotation about the rhodium-olefin bond is significantly hindered, likewise in some of the analogous alkyne rhodium compounds trans- $[RhCl(RC \equiv CR')(Pr_2^i AsCH_2CH_2OMe)_2]$ (R = Me or SiMe₃; R' = Ph).

Alkyne, Allene, Vinylidene and Allenylidene Rhodium Complexes prepared from Alkynes.—Due to the lability of the Rh-C₂H₄ bond in complex 5, the synthesis of the alkyne complexes 12–16 is straightforward and can be performed in pentane at -78 °C. Even under these conditions, the displacement of the olefin occurs readily and gives the products in virtually quantitative yield. Whereas 12–15 are yellow or orange microcrystalline solids, compound 16 is an oil at room temperature and somewhat more air-sensitive than the solid counterparts. For all the alkyne complexes correct elemental analyses have been obtained. The most characteristic feature in the ¹H NMR spectra of 12 and 13 is the doublet at δ 3.8–4.8 which is assigned to the \equiv CH proton of the co-ordinated alkyne. The ¹³C NMR spectra of 12–16 display two resonances at δ 60–90 (for 14 one is observed at δ 108) corresponding to the carbon atoms of the C \equiv C unit.

In contrast to the reaction of 5 with HC=CPh and HC=CCO2Me a vinylidene instead of an alkyne rhodium complex is formed on treatment of the ethene compound with HC≡CMe or HC≡CBu^t. If the corresponding 1-alkyne (not in a large excess) is added at -78 °C to a pentane solution of 5 and the reaction mixture slowly warmed to room temperature, a characteristic change of colour from yellow to violet occurs and after stirring for 20 min (R = Me) or 3 h (R = Bu^t) the products 19 and 20 (Scheme 3) are generated in about 90% yield. Although attempts to isolate an intermediary species in these reactions have failed, we nevertheless believe that an alkyne rhodium compound trans-[RhCl(HC≡CR)(Prⁱ2AsCH2- CH_2OMe_2 (R = Me or Bu^t) is initially formed. If the reaction mixture obtained from 5 and HC=CBut is worked-up after 1 h (instead of 3 h), upon removal of the solvent an oily residue remains whose IR spectrum shows a band at 1833 cm⁻¹ typical for a co-ordinated alkyne. In the IR spectra of the final product 20 an absorption at 1641 cm⁻¹ is observed which corresponds to the C=C stretching frequency of the vinylidene ligand.

The analogous phenyl- and carboxymethyl-substituted vinyl-

idene complexes 17 and 18 are prepared by UV irradiation of benzene solutions of 12 and 13 at room temperature. After 1 h the isomerization is complete. Whereas 17, 18 and 20 are dark violet, rather low-melting solids, compound 19 is a violet oil which does not crystallize at room temperature. Diagnostic in the 1H NMR spectra is a doublet at δ 0.3–1.8 for the vinylidene C=CHR proton, and in the ^{13}C NMR spectra a low-field signal at δ 282–293 which corresponds to the metal-bonded carbon atom of the Rh=C=CHR moiety.

The reaction of 5 with HC≡CMe takes a different course if a large excess of the alkyne (5: HC \equiv CMe $\approx 1:90$) is used. Under these conditions, instead of the methylvinylidene complex 19, the isomeric allene rhodium compound 21 is obtained. The internal alkyne MeC=CBut behaves similarly and upon treatment with 5 gives the tert-butylallene derivative 22 in excellent yield. The spectroscopic data of 22 strongly support the proposal (see Scheme 4) that it is the unsubstituted double bond of the allene which is co-ordinated to the metal. The ¹³C NMR spectrum in particular is similar to those of the related bis(triisopropylphosphine) and bis(triisopropylarsine) rhodium complexes trans-[RhCl{CH₂=C=CH(CO₂Et)}(PPrⁱ₃)₂]¹³ and trans-[RhCl(CH₂=C=CHBuⁱ)(AsPrⁱ₃)₂],¹⁰ the first of which has been structurally characterized by X-ray crystallography. Concerning the mechanism of the reaction of 5 with CH₃C≡CR $(R = H \text{ or } Bu^t)$, we assume that in the primary step the expected (but very labile) alkyne complex trans-[RhCl(CH₃C≡CR)-(Pri2AsCH2CH2OMe)2] is formed which rearranges via a short-lived RhH(η^3 -CH₂C₂CH₃) intermediate to the final product. There is some precedent for the metal-initiated transformation of an alkyne to the isomeric allene insofar as Richards and co-workers 14 as well as the authors 15 have described the formation of substituted allene rhenium and iridium complexes from reactive metal precursors and CH₃C≡CPh or CH₃C≡CCH₃, respectively.

The 1H NMR spectrum of compound 21 deserves some comments. It shows three signals for the allene protons, one at relatively high field at δ 2.3 (in C_6D_6) for the equivalent protons of the metal-bound CH_2 group and two at lower field at δ 5.25 and 5.41 for the non-equivalent hydrogens (H_{exo} and H_{endo}) of the unco-ordinated CH_2 allene unit. This assignment, which is consistent with data for analogous systems, 16 together with the appearance of four doublets for the diastereotopic CH_3 protons of the isopropyl groups, indicates a hindered rotation around the allene-to-rhodium bond and an effectively rigid structure of the whole molecule. Evidence for the non-fluxional behaviour on the NMR time-scale of the C_3H_4 ligand in 21 is equally provided by the ^{13}C NMR spectrum which reveals a large difference in the chemical shift between the signals of the two CH_2 carbons (δ 95.51 and 6.63).

The buta-1,3-diyne derivatives MeC≡C-C≡CMe and Me₃-SiC=C-C=CSiMe, react with compound 5 in pentane at low temperature to give instead of the expected dinuclear species the mononuclear complexes 23 and 24 in virtually quantitative yield. We assume that it is the steric bulk of the arsinoether ligands which prevents the co-ordination of two RhCl-(Pri₂AsCH₂CH₂OMe)₂ units to the diyne molecule. The two compounds 23 (an orange-yellow low-melting solid) and 24 (an orange oil) are soluble in all common organic solvents, including pentane and hexane, and are only slightly airsensitive. The structural proposal shown in Scheme 4 is particularly supported by the IR spectra in which a band at 2197 (23) or 2120 cm⁻¹ (24) assigned to v(C = C) of a free alkyne moiety is observed apart from an absorption at 1904 (23) or 1828 cm⁻¹ (24) for a co-ordinated alkyne. ¹⁷ In accordance with this, there are also two signals in the ¹H NMR spectrum of 23 for the two different methyl groups and in that of 24 for the two different trimethylsilyl groups. Equally, there are four signals in the 13C NMR spectra due to the carbon atoms of the coordinated and unco-ordinated triple bond.

The synthesis of the allenylidene rhodium complexes 29-32 has been achieved as outlined in Scheme 5. In the first

Scheme 5

step, treatment of the ethene derivative 5 with the alkynol HC \equiv C-CRR'OH leads, for R = R' = alkyl at room temperature and for R = R' = aryl even at -78 °C, to the formation of the vinylidenes 25–28 which after column chromatography have been isolated as violet low-melting crystalline solids. The assumption that these compounds are formed *via* the isomeric alkyne complexes *trans*-[RhCl(HC \equiv CCRR'OH)(Pr $^{i}_{2}$ AsCH $_{2}$ CH $_{2}$ OMe) $_{2}$] could not be substantiated by isolating an intermediate although a rapid colour change from orange to yellow after the addition of 1,1-diphenylprop-2-yne-1-ol to a pentane solution of 5 at -78 °C may be due to the formation of such a species. As far as the spectroscopic data of 25–28 are concerned, the most typical features are, as for the related

compounds 17–20, the low-field signals in the ^{13}C NMR spectra at δ 283–287 and 110–122, which are assigned to the C^{α} and C^{β} vinylidene carbon atoms. In the IR spectra, a fairly broad band at 3400–3450 cm⁻¹ is indicative of an OH group.

Whereas solutions of 25 and 26 in hexane or benzene rapidly decompose in the presence of Al_2O_3 or acidic substrates, compounds 27 and 28 react with alumina by abstraction of water to give the allenylidene rhodium(1) derivatives 29 and 30 in 80–90% yield. The red solids which have been characterized by elemental analysis are moderately air-sensitive and readily soluble in most organic solvents. They can be transformed to the cyclopentadienyl complexes 31 and 32 upon treatment with NaC_5H_5 in tetrahydrofuran (thf). After chromatographic

Scheme 6

work-up, the allenylidene half-sandwiches are isolated as turquoise-blue oily substances. We note that the spectroscopic data of **29** and **30** are distinctly different from those of the corresponding rhodium vinylidenes **17–20** and **25–28** and in some respects resemble those of organic allenes. ¹⁸ Most diagnostic are the strong C=C=C stretchings in the IR spectra at *ca*. 1875 cm⁻¹ (for **29**, **30**) and *ca*. 1910 cm⁻¹ (for **31**, **32**) and the three low-field resonances in the ¹³C NMR spectra at δ 160–250. In this context it should be mentioned that in the spectra of the square-planar rhodium allenylidenes **29** and **30** the signal of C^{α} of the Rh=C=C=C chain appears at somewhat higher field than that of C^{β} , while for **31** and **32** this situation is reversed.

Carbene and Diazoalkane Rhodium Derivatives prepared from Diazoalkane Precursors.—In contrast to the bis(triisopropylarsine) complex trans-[RhCl(C₂H₄)(AsPrⁱ₃)₂] which upon treatment with N₂CPh₂ yields trans-[RhCl(N₂CPh₂)-(AsPri₃)₂], 19 the arsinoether derivative 5 reacts with diphenyldiazomethane in pentane under slightly reduced pressure (ca. 50 Torr) to give initially a brown-green oily product which in benzene solution after prolonged stirring (5 h) or short photolysis (20 min) affords the diphenylcarbene rhodium(1) compound trans-[RhCl(=CPh₂)(Prⁱ₂AsCH₂CH₂OMe)₂] 33 in moderate yield (Scheme 6). The p-tolyl derivative N₂C-(C₆H₄Me-p)₂ behaves similarly and gives trans-[RhCl- ${=C(C_6H_4Me-p)_2}(Pr_2^iAsCH_2CH_2OMe)_2$ 34. The browngreen intermediate which is also formed in this case seems to be a 1:1 adduct between [RhCl(Pri₂AsCH₂CH₂OMe)₂] and N₂CR₂ in which the diaryldiazomethane moiety is possibly bonded via N and C to the metal. If an 'end-on' co-ordination mode as in trans-[RhCl(N₂CPh₂)(PPrⁱ₃)₂]²⁰ were present, an absorption in the IR spectrum at 1900-2000 cm-1 would be expected which is, however, absent. Instead, a band of medium intensity at about 1670 cm⁻¹ is observed. Since the ¹H NMR spectrum of the intermediate reveals that the arsinoether ligands are not equivalent, we assume that one of them is monodentate and one bidentate and that the rhodium centre is co-ordinated in an octahedral fashion. There is some precedent for such a bonding mode of a diazoalkane ligand. Stone and co-workers 21 have previously described the synthesis of the complexes [IrCl{N₂C(CF₃)₂}(PPh₃)₂] and cis-[Pt{N₂-C(CF₃)₂(PPh₃)₂ in which according to the spectroscopic data a C,N-chelated $N_2C(CF_3)_2$ unit is present.

The rhodium carbenes 33 and 34 which are low-melting air-sensitive materials have been characterized by elemental analysis and NMR spectroscopy. The most characteristic feature is the low-field signal for the carbene carbon atom in the ¹³C NMR spectrum which displays a large Rh–C coupling of 32–33 Hz. It should be mentioned that in the reaction of 5 with diphenyldiazomethane small amounts of the trisubstituted ethene derivative Ph₂C=CHCH₃ are also formed. This is obtained on a catalytic route from C₂H₄ and N₂CPh₂ by using compound 3 as catalyst. ^{20,22}

The diazocarbonyl derivatives N_2 CHC(O)Ph and N_2 CPh-C(O)Ph react with 5 to give complexes 35 and 36 in which the intact N_2 CRR' moiety is probably bonded 'end-on' through the

nitrogen atom to the metal centre. Diagnostic for this type of co-ordination is a N-N stretching frequency in the IR at $1920-1930~{\rm cm}^{-1}$ and a signal in the ^{13}C NMR spectrum for the N_2C carbon atom at δ 83.06 (35) or 101.09 (36). Despite the fact that both compounds are thermally not very stable (decomposition temperature about 30 °C), all attempts to transform them to the corresponding rhodium carbenes *trans*-[RhCl{=CR(COPh)}(Pr $^i_2AsCH_2CH_2OMe)_2$] have remained unsuccessful.

Experimental

All reactions were carried out under an atmosphere of argon by Schlenk-tube techniques. The starting materials $HAsPr^{i}_{2}$, 9 [{RhCl($C_{8}H_{14}$)₂}₂] 1^{23} and [{RhCl($C_{2}H_{4}$)₂}₂] 3^{24} were prepared by published methods. The alkenes and alkynes were commercial products from Aldrich and ABCR. The NMR spectra were recorded on Bruker AC 200 and Bruker AMX 400 spectrometers (s = singlet, d = doublet, t = triplet, q = quartet, spt = septet, m = multiplet, br = broadened signal), the IR spectra on a Perkin-Elmer 1420 spectrometer and the mass spectra on Varian CH7 MAT and Finnigan 90 MAT instruments. Melting and decomposition points were determined by differential thermal analysis.

Preparations.—Pri2AsCH2CH2OMe I. In a three-necked flask (250 cm³) a solution of HAsPrⁱ₂ (5.20 g, 32.0 mmol) in thf (60 cm³) was treated at 0 °C dropwise with a 1.14 mol dm⁻³ solution of LiBu (32.0 cm³) in hexane. After warming to room temperature, the solution was stirred for 30 min and then heated under reflux for 1 h. At reflux temperature, a solution of ClCH₂CH₂OMe (3.30 g, 35.0 mmol) in thf (5 cm³) was added dropwise to the reaction mixture which slowly led to the formation of a white microcrystalline precipitate. After 30 min under reflux, the solution was cooled to room temperature and then 100 cm³ of a saturated aqueous solution of NH₄Cl were added. The ether phase was separated, the aqueous solution was extracted three times with diethyl ether (50 cm³ each), and the combined ethereal phases were dried over Na₂SO₄ for 5 h. The sodium salt was filtered off, the ether was removed and the oily residue was distilled under reduced pressure (ca. 2 Torr). At 50-51 °C, a colourless air-sensitive liquid was obtained (D = 1.047g cm⁻³) which for analytical characterization was converted with MeI to the arsonium salt [MeAs(Pri)2CH2CH2OMe]I (Found: C, 33.35; H, 6.85. Calc. for C₁₀H₂₄AsIO: C, 33.15; H, 6.70%). NMR: 1 H (400 MHz, $C_{6}D_{6}$), δ 3.48 (m, 2 H, CH_2OCH_3), 3.13 (s, 3 H, CH_2OCH_3), 1.65 (m, 2 H, AsCH₂), 1.63 [spt, J(HH) 7.2, 2 H, AsCHCH $_3$], 1.08 and 1.05 [both d, J(HH) 7.2 Hz, 12 H, AsCHCH $_3$]; ¹³C (100.6 MHz, C $_6$ D $_6$), δ 72.32 (s, CH₂OCH₃), 58.04 (s, CH₂OCH₃), 23.60 (s, AsCHCH₃), 21.95 (s, AsCH₂), 20.93 and 20.04 (both s, AsCHCH₃).

[{RhCl(C_8H_{14})(Pr i_2 AsCH $_2$ CH $_2$ OMe)} $_2$] **2.** A suspension of compound 1 (60 mg, 0.08 mmol) in pentane (10 cm 3) was treated with I (35 μ l, 0.16 mmol) and stirred for 30 min at room temperature. The solution was brought to dryness *in vacuo*, the

oily residue was dissolved in benzene (0.3 cm³), and the solution was chromatographed on Al_2O_3 (neutral, activity grade V, height of column 3 cm). With benzene–hexane (1:1), an orange-yellow fraction was eluted from which the solvent was removed in vacuo. The oily residue was recrystallized from thf–pentane (1:10) to give, after cooling to -78 °C, orange-yellow crystals: yield 61 mg (81%), m.p. 35 °C (decomp.) (Found: C, 43.20; H, 7.55. Calc. for $C_{34}H_{70}As_2Cl_2O_2Rh_2$: C, 43.55; H, 7.55%). NMR: 1H (200 MHz, C_6D_6), δ 3.71–3.18, 2.70–2.35 and 1.59–1.40 (all m, 28 H, C_8H_{14}), 3.66 (m, 4 H, CH_2OCH_3), 3.14 (s, 6 H, CH_2OCH_3), 1.99 [spt, J(HH) 7.2, 4 H, $AsCHCH_3$], 1.63 (m, 4 H, $AsCH_2$), 1.33 and 1.13 [both d, J(HH) 7.2 Hz, 24 H, $AsCHCH_3$].

[{RhCl(C_2H_4)(Pr¹₂AsCH₂CH₂OMe)}₂] **4.** A solution of compound **3** (50 mg, 0.13 mmol) in diethyl ether (2 cm³) was treated dropwise with a solution of **I** (54 μ l, 0.26 mmol) in diethyl ether (3 cm³) and stirred for 1 h at room temperature. The solvent was removed, the oily residue was thoroughly dried in vacuo (10⁻³ Torr) and then recrystallized from pentane (10 cm³) at -78 °C. Orange needles were obtained which were repeatedly washed with small amounts of pentane (0 °C) and dried: yield 83 mg (83%), m.p. 45 °C (decomp.) (Found: C, 34.05; H, 6.85. Calc. for C₂₂H₅₀As₂Cl₂O₂Rh₂: C, 34.15; H, 6.50%). NMR: ¹H (200 MHz, C₆D₆), δ 3.58 (m, 4 H, CH₂OCH₃), 3.15 (br s, 8 H, C₂H₄), 3.09 (s, 6 H, CH₂OCH₃), 1.88 [spt, J(HH) 7.1, 4 H, AsCHCH₃], 1.58 (m, 4 H, AsCHCH₃].

trans-[RhCl(C₂H₄)(Prⁱ₂AsCH₂CH₂OMe)₂] 5. A solution of compound 3 (50 mg, 0.13 mmol) in diethyl ether (10 cm³) was treated with I (108 µl, 0.52 mmol) and stirred for 1 h at room temperature. A change of colour from orange to orange-red was observed. The solvent was removed in vacuo, the oily residue was dissolved in hexane (1 cm³), and the solution was chromatographed on Al₂O₃ (neutral, activity grade V, height of column 3 cm). With hexane, an orange-yellow fraction was eluted which was brought to dryness in vacuo. The residue was recrystallized from pentane to give, after cooling to -78 °C. orange-yellow crystals: yield 123 mg (78%), m.p. 41 °C (decomp.) (Found: C, 39.45; H, 7.85. Calc. for $C_{20}H_{46}As_2$ $ClO_2Rh: C$, 39.60; H, 7.65%). NMR: ¹H (200 MHz, C_6D_6), δ 3.69 (m, 4 H, CH_2OCH_3), 3.15 (s, 6 H, CH_2OCH_3), 2.81 [d, J(RhH) 2.2, 4 H, C₂H₄], 2.29 [spt, J(HH) 7.2, 4 H, AsCHCH₃], 1.82 (m, 4 H, AsCH₂), 1.34 and 1.19 [both d, J(HH) 7.2 Hz, 24 H, AsCHC H_3]; ¹³C (50.3 MHz, C₆D₆), δ 70.19 (s, CH₂OCH₃), 58.09 (s, CH₂OCH₃), 34.76 [d, J(RhC) 14.6 Hz, C_2H_4], 24.34 (s, As CHCH₃), 20.70 and 20.20 (both s, AsCHCH₃), 17.30 (s, AsCH₂).

trans-[RhCl(CO)(Prⁱ₂AsCH₂CH₂OMe)₂] **6**. Carbon monoxide was passed through a solution of **5** (61 mg, 0.10 mmol) in pentane (10 cm³) at room temperature for 10 s. After the solution was stirred for 15 min, it was concentrated *in vacuo* until the first crystals precipitated. Further cooling to -78 °C led to the formation of a pale yellow microcrystalline solid which was separated, repeatedly washed with pentane (0 °C) and dried: yield 60 mg (98%), m.p. 50 °C (decomp.) (Found: C, 38.10; H, 7.20. Calc. for C₁₉H₄₂As₂ClO₃Rh: C, 37.60; H, 7.00%). IR (KBr), v(CO) 1974 cm⁻¹. NMR: ¹H (200 MHz, C₆D₆), δ 3.77 (m, 4 H, CH₂OCH₃), 3.34 (s, 6 H, CH₂OCH₃), 2.49 [spt, *J*(HH) 7.2, 4 H, AsCHCH₃], 2.19 (m, 4 H, AsCHC₃]; ¹³C (50.3 MHz, C₆D₆), δ 188.51 [d, *J*(RhC) 71.5 Hz, CO], 70.24 (s, CH₂OCH₃), 58.04 (s, CH₂OCH₃), 26.14 (s, AsCHCH₃), 21.29 (s, AsCH₂), 20.25 and 19.81 (both s, AsCHCH₃).

trans-[RhCl(CNBu¹)(Pr¹₂AsCH₂CH₂OMe)₂] 7. A solution of 5 (53 mg, 0.09 mmol) in pentane (8 cm³) was treated at -78 °C with tert-butyl isocyanide (10 µl, 0.09 mmol) and, after warming to room temperature, stirred for 15 min. A gradual brightening of the yellow solution was observed. The solvent was removed in vacuo, and the oily residue was recrystallized from pentane to give, after cooling to -78 °C, yellow airsensitive crystals: yield 53 mg (89%), m.p. 38 °C (decomp.)

(Found: C, 41.65; H, 7.95; N, 2.00. Calc. for $C_{23}H_{51}As_2Cl-NO_2Rh$: C, 41.75; H, 7.75; N, 2.10%). IR (C_6H_6), ν (C \equiv N) 2141 and 2104 cm $^{-1}$. NMR: 1H (200 MHz, C_6D_6), δ 3.92 (m, 4 H, CH_2OCH_3), 3.18 (s, 6 H, CH_2OCH_3), 2.32 [spt, J(HH) 7.1, 4 H, $AsCHCH_3$], 2.25 (m, 4 H, $AsCH_2$), 1.44 and 1.28 [both d, J(HH) 7.1 Hz, 24 H, $AsCHCH_3$], 1.11 [s, 9 H, C(CH $_3$)₃].

[RhH₂Cl(Prⁱ₂AsCH₂CH₂OMe)₂] **8.** Hydrogen was passed through a solution of **5** (57 mg, 0.09 mmol) in pentane (7 cm³) at room temperature for 30 s. A change of colour from orange-yellow to red was observed. After the solution was stirred for 5 min, the solvent was removed *in vacuo*, the oily residue was dissolved in hexane (3 cm³), and the solution was chromatographed on Al₂O₃ (neutral, activity grade V, height of column 3 cm). With diethyl ether–hexane (2:1), an orange-red fraction was eluted which was brought to dryness *in vacuo*. The remaining orange-red oil was thoroughly dried *in vacuo* (10⁻³ Torr): yield 54 mg (99%) (Found: C, 37.30; H, 7.40. Calc. for C₁₈H₄₄As₂ClO₂Rh: C, 37.20; H, 7.65%). IR (C₆H₆), v(RhH) 2079 cm⁻¹. NMR: ¹H (200 MHz, C₆D₅CD₃), δ 3.73 (m, 4 H, CH₂OCH₃), 3.17 (s, 6 H, CH₂OCH₃), 2.12 [spt, *J*(HH) 6.9, 4 H, AsCHCH₃], 1.87 (m, 4 H, AsCH₂), 1.27 and 1.25 [both d, *J*(HH) 6.9, 24 H, AsCHCH₃], -23.06 [d, *J*(RhH) 19.7 Hz, 2 H, RhH₂].

trans-[RhCl(C₂H₄)(HAsPrⁱ₂)₂] 9. A solution of 5 (37.mg, 0.06 mmol) in $[^{2}H_{6}]$ benzene (0.5 cm³) was irradiated at room temperature in an NMR tube for 10 h. A gradual change of colour from orange-yellow to red was observed. The solution was transferred into a Schlenk tube and slowly condensed into another cooled $(-78 \, ^{\circ}\text{C})$ Schlenk tube. The clear condensate was identified as methyl vinyl ether by ¹H and ¹³C NMR data. ²⁵ The orange oily residue in the first Schlenk tube was dried in vacuo (10⁻³ Torr) and spectroscopically identified as 9. An independent synthesis of 9 is as follows. A solution of 3 (39 mg, 0.10 mmol) in diethyl ether (5 cm³) was treated with four equivalents of HAsPri₂ (67 µl, 0.40 mmol). After stirring for 20 min at room temperature, the solvent was removed and from the residue, after recrystallization from pentane (-78 °C), an orange-yellow microcrystalline solid was obtained: yield 38 mg (78%), m.p. 118 °C (decomp.) (Found: C, 34.40; H, 7.10. Calc. for C₁₄H₃₄As₂ClRh: C, 34.25; H, 7.00%). NMR: ¹H (200 MHz, C_6D_6), δ 2.96 [d, J(RhH) 2.4, 4 H, C_2H_4], 2.53 (m, 2 H, AsH), 2.12 [spt, J(HH) 7.1, 4 H, AsCHCH₃], 1.21 and 1.13 [both d, J(HH) 7.1 Hz, 24 H, AsCHCH₃]; ¹³C (50.3 MHz, C₆D₆), δ 31.93 [d, J(RhC) 13.9 Hz, C_2H_4], 25.30 (s, AsCHCH₃), 22.60 and 21.54 (s, AsCHCH₃).

trans- $[RhCl\{H_2C=CHC(O)Me\}(Pr_2^iAsCH_2CH_2OMe)_2]$ 10. A solution of 5 (61 mg, 0.10 mmol) in pentane (10 cm³) was treated with methyl vinyl ketone (8 µl, 0.10 mmol) and stirred for 45 min at room temperature. A gradual change of colour from orange to orange-red was observed. The solvent was removed in vacuo, and the residue was recrystallized from pentane (5 cm³) to give, after cooling to -78 °C, orange-red crystals: yield 63 mg (98%), m.p. 36 °C (Found: C, 40.45; H, 7.50. Calc. for $C_{22}H_{48}As_2ClO_3Rh$: C, 40.75; H, 7.45%). IR (KBr), v(C=O) 1673 cm⁻¹. NMR: ¹H (200 MHz, C_6D_6), δ 3.89 [br dd, ³ $J(HH_{trans})$ 10.7, ³ $J(HH_{cis})$ 7.1, 1 H, $H_2C=CH_1$, 3.78 (M, 4 H, CH_2OCH_3), 3.09 (s, 6 H, CH_2OCH_3), 3.07 [br d, ${}^3J(HH_{trans})$ 10.7, 1 H, H_2 C=CH], 2.59 [br d, 3J (HH_{cis}) 7. $\bar{1}$, 1 H, H_2 C=CH], 2.39 [spt, J(HH) 6.8, 4 H, AsCHCH₃], 2.30 [s, 3 H, C(O)CH₃], 1.64 (m, 4 H, AsCH₂), 1.34 and 1.18 [both d, J(HH) 6.8 Hz, 24 H, AsCHC H_3]; ¹³C (50.3 MHz, C₆D₆), δ 204.76 [d, J(RhC)1.8, C(O)CH₃], 70.15 (s, CH₂OCH₃), 58.07 (s, CH₂OCH₃), 48.17 [d, J(RhC) 14.5, H₂C=CH], 31.05 [s, C(O)CH₃], 28.57 [d, J(RhC) 14.0 Hz, $H_2C=CH$], 25.14 (s, As $CHCH_3$), 21.15 and 20.17 (both s, AsCHCH₃), 18.12 (s, AsCH₂).

 $[Rh(C_5H_5){=C=C=CPh(C_6H_4Me-o)}(Pr_2^iAsCH_2CH_2-iCH_2)]$ OMe)] 32. This compound was prepared as described for 31, using 30 (94 mg, 0.12 mmol) and NaC_5H_5 (53 mg, 0.60 mmol) as starting materials. A turquoise-blue oil was obtained: yield $48 \text{ mg} (68\%) (\text{Found: C}, 61.00; \text{H}, 6.30. \text{ Calc. for C}_{30} \text{H}_{38} \text{AsORh:}$ C, 60.80; H, 6.45%). MS (70 eV) 592 (M^+). IR (C_6H_6), v(C=C=C) 1912 cm⁻¹. NMR: ¹H (200 MHz, C_6D_6), δ 8.56–8.53 (m, 1 H, o-H of o-C₆ H_4 CH₃), 8.23–8.19 (m, 2 H, o-H of C₆ H_5), 7.26–6.95 (m, 6 H, *m*-H and *p*-H of C_6H_5 and o- $C_6H_4CH_3$), 5.01 [d, J(RhH) 0.7, 5 H, C_5H_5], 3.45 (m, 2 H, C_4CH_3), 3.03 (s, $\bar{3}$ H, CH₂OCH₃), 2.26 [spt, J(HH) 7.2, 2 H, AsCHCH₃], 2.17 (s, 3 H, o-C₆H₄CH₃), 1.59 (m, 2 H, AsCH₂), 0.96 and 0.93 [both d, J(HH) 7.2 Hz, 12 H, AsCHCH₃]; ¹³C (50.3 MHz, C₆D₆), δ 227.52 [d, J(RhC) 67.7, =C=C=C], 207.85 [d, J(RhC) 16.0, =C=C=C], 163.18 (s, =C=C=C), 147.10 and 146.84 (both s, C¹ of C_6H_5 and o- $C_6H_4CH_3$), 135.98 (s, C^2 of o- $C_6H_4CH_3$), 133.59, 130.32, 129.97, 127.76, 126.85, 126.21 and 125.49 (all s, C²⁻⁶ of C_6H_5 and C^{3-6} of $o-C_6H_4CH_3$), 81.51 [d, J(RhC) 4.3 Hz, C_5H_5], 70.53 (s, CH_2OCH_3), 58.11 (s, CH_2OCH_3), 26.30 (s, AsCHCH₃), 22.77 (s, o-C₆H₄CH₃), 19.64 and 19.05 (both s, AsCHCH₃), 14.23 (s, AsCH₂).

trans-[RhCl(=CPh₂)(Prⁱ₂AsCH₂CH₂OMe)₂] 33. A solution of 5 (169 mg, 0.28 mmol) in pentane (12 cm³) was treated at -78 °C with a solution of diphenyldiazomethane (119 mg, 0.60 mmol) in pentane (3 cm³). After warming to room temperature the solution was stirred under reduced pressure (≈ 50 Torr) for 15 min. The brown-green reaction mixture was then concentrated to 1 cm³ in vacuo, and the concentrate was chromatographed on Al₂O₃ (neutral, activity grade V, height of column 3 cm). With hexane, first a violet fraction was eluted which contained the excess of diphenyldiazomethane. The second brown-green fraction was brought to dryness in vacuo, the oily residue was dissolved in benzene (0.5 cm³), and the solution was either stirred at room temperature for 5 h or irradiated with UV light for 20 min. After the solvent was removed, the oily residue was dissolved in hexane (1 cm³), and the solution was chromatographed on Al₂O₃ (neutral, activity grade V, height of column 3 cm). With hexane, a yellow-green fraction was eluted which after removal of the solvent gave an oily residue that was recrystallized from pentane (2 cm³) to give, after cooling to -78 °C, a green-yellow solid which melts above 10 °C: yield 63 mg (30%) (Found: C, 50.05; H, 6.80. Calc. for $C_{31}H_{52}As_2ClO_2Rh$: C, 50.00; H, 7.05%). NMR: ¹H (200 MHz, C_6D_6), δ 7.97 [dd, ³J(HH) 7.1, ⁴J(HH) 1.1, 4 H, o-H of C_6H_5], 7.11–6.90 (m, 6 H, m-H and p-H of C_6H_5), 3.64 (m, 4 H, CH₂OCH₃), 3.13 (s, 6 H, CH₂OCH₃), 2.15 [spt, J(HH) 7.2, 4 H, AsCHCH₃], 1.80 (m, 4 H, AsCH₂), 1.28 [d, J(HH) 7.1, 12 H, AsCHC H_3], 1.08 [d, J(HH) 7.3 Hz, 12 H, AsCHC H_3]; ¹³C (50.3 MHz, C_6D_6), δ 313.76 [d, J(RhC) 33.0 Hz, Rh=C], 159.91 (s, C^1 of C_6H_5), 131.71, 130.10 and 129.74 (all s, C^{2-6} of C_6H_5), 70.42 (s, CH_2OCH_3), 57.91 (s, CH_2OCH_3), 25.62 (s, AsCHCH₃), 21.07 and 19.98 (both s, AsCHCH₃), 20.13 (s,

trans- $[RhCl{=C(C_6H_4Me-p)_2}(Pr_2^iAsCH_2CH_2OMe)_2]$ 34. This compound was prepared as described for 33, using 5 (180 mg, 0.30 mmol) and di(p-tolyl)diazomethane (132 mg, 0.60

mmol) as starting materials. A bright green oil was obtained: yield 142 mg (61%) (Found: C, 51.00; H, 7.45. Calc. for C₃₃H₅₆As₂ClO₂Rh: C, 51.30; H, 7.30%).
