

Platinum Metal Complexes of Mixed Thia/Oxa Ionophores. The Synthesis and Single-crystal X-Ray Structures of $[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ and $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6 \cdot \text{H}_2\text{O}$ ($[\text{15}] \text{aneS}_2\text{O}_3 = 1,4,7\text{-trioxa-10,13-dithiacyclopentadecane}$)[†]

Alexander J. Blake, Gillian Reid, and Martin Schröder*

Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh EH9 3JJ

The synthesis and characterisation of a series of mixed thia/oxa donor macrocyclic complexes *cis*- $[\text{MCl}_2([\text{15}] \text{aneS}_2\text{O}_3)]$, $[\text{M}([\text{15}] \text{aneS}_2\text{O}_3)_2]^{2+}$ ($\text{M} = \text{Pd}$ or Pt), $[\text{MCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ ($\text{M} = \text{Rh}$ or Ir), and $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ ($[\text{15}] \text{aneS}_2\text{O}_3 = 1,4,7\text{-trioxa-10,13-dithiacyclopentadecane}$) are described. Reaction of MCl_2 ($\text{M} = \text{Pd}$ or Pt) with one molar equivalent of $[\text{15}] \text{aneS}_2\text{O}_3$ affords the complex *cis*- $[\text{MCl}_2([\text{15}] \text{aneS}_2\text{O}_3)]$; addition of a second equivalent affords the bis complex cations $[\text{M}([\text{15}] \text{aneS}_2\text{O}_3)_2]^{2+}$. The complex $[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ crystallises in the monoclinic space group $P2_1/c$, $a = 10.394(4)$, $b = 14.003(4)$, $c = 11.675(5)$ Å, $\beta = 104.22(3)$, $U = 1\,647$ Å³, and $Z = 2$. The single-crystal X-ray structure shows the Pd^{II} occupying a crystallographic inversion centre, with square-planar co-ordination by the $[\text{15}] \text{aneS}_2\text{O}_3$ ionophores through the thioether S-donors, $\text{Pd-S}(1) 2.314\,9(10)$, $\text{Pd-S}(4) 2.301\,7(10)$ Å. The O-donors point away from the Pd^{II} to give a relatively flattened complex. Reaction of $\text{MCl}_3 \cdot 3\text{H}_2\text{O}$ ($\text{M} = \text{Rh}$ or Ir) with two molar equivalents of $[\text{15}] \text{aneS}_2\text{O}_3$ affords the complex cations $[\text{MCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$. Treatment of $[\text{RuCl}_2(\text{PPh}_3)_3]$ with two molar equivalents of $[\text{15}] \text{aneS}_2\text{O}_3$ gives the complex cation $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$. The complex $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6 \cdot \text{H}_2\text{O}$ crystallises in the orthorhombic space group $Pbcn$, $a = 19.252\,6(14)$, $b = 25.968(3)$, $c = 18.903\,3(23)$ Å, $U = 9\,451$ Å³, and $Z = 8$. The single-crystal X-ray structure shows octahedral co-ordination at Ru^{II} with the Cl^- and PPh_3 ligands mutually *trans*, $\text{Ru-Cl } 2.458(3)$, $\text{Ru-P } 2.319(3)$ Å. The $[\text{15}] \text{aneS}_2\text{O}_3$ ligands are bound exocyclically to Ru^{II} via four thioether S-donors, $\text{Ru-S } 2.390(3)$, $2.394(3)$, $2.395(3)$, $2.405(3)$ Å. The O-donors of $[\text{15}] \text{aneS}_2\text{O}_3$ are not bound to the metal centre but, unlike the complex $[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2]^{2+}$, are directed towards the face occupied by the Cl^- ligand and away from the sterically bulky PPh_3 ligand. The $[\text{15}] \text{aneS}_2\text{O}_3$ ligands in $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ therefore form a cavity at one face of the metal centre in which the co-ordinated Cl^- ligand sits.

Macrocyclic ligands incorporating recognition sites capable of binding both hard- and soft-metal guest ions are of considerable current interest since they may facilitate electron-transfer processes and serve as models of relevance to biological processes.¹⁻⁵ They may also provide effective systems with which to monitor alkali-metal concentrations in solution, due to the allosteric effect of binding two metal ions in close proximity to each other.²⁻⁵ One approach utilising ferrocene derivatives, which show highly reversible $\text{Fe}^{\text{II}}\text{-Fe}^{\text{III}}$ couples, as potential sensors for substrate cations, is well established.^{3,4} For example, it has been shown recently that the binding of Li^+ to aza-15-crown-5 (1,4,7,10-tetraoxa-13-azacyclopentadecane, $[\text{15}] \text{aneNO}_4$) covalently attached to a ferrocene moiety results in a shift in the $\text{Fe}^{\text{II}}\text{-Fe}^{\text{III}}$ couple to more anodic potentials.³ Green and co-workers⁵ have adopted an alternative approach, using dithiolate donors incorporated in the side chains of crown ethers to attach the ionophore to $[\text{M}(\eta^5\text{-C}_5\text{H}_5)_2]^{2+}$ ($\text{M} = \text{Mo}$ or W) fragments.

We have been investigating the co-ordination chemistry of homoleptic thioether crowns,⁶ and proposed that mixed thioether/oxaether crowns would bind soft second- and third-row metal ions *via* the S-donors, leaving the O-donors unco-ordinated and therefore available for binding to Main Group 1 and 2 ions, amino acids, or related cations/anions. However, this approach necessitates *exo* co-ordination of transition-metal ions to the macrocyclic ring since *endo* co-ordination would block guest co-ordination *via* the O-donors. Co-ordination of

$[\text{15}] \text{aneS}_2\text{O}_3$

transition-metal ions *exo* to a thioether crown has been noted,^{7,8} and indeed this is proposed as the first step in co-ordination, since the metal-free thioether crowns typically adopt conformations in which the S-donors lie in *exo* positions.^{8,9} However, *exo* complexes are not stabilised by the macrocyclic effect, only by chelate formation. In addition, monodentate thioethers are often kinetically labile, particularly with first-row metal centres.¹⁰ We therefore undertook a preliminary investigation into the co-ordination chemistry of $[\text{15}] \text{aneS}_2\text{O}_3$ to determine whether this simple ionophore would form stable platinum-metal complexes *via* chelation of the two thioether S-donors. We describe herein the synthesis of a series of complexes of $[\text{15}] \text{aneS}_2\text{O}_3$ with the platinum-metal ions Pd^{II} , Pt^{II} , Rh^{III} , Ir^{III} , and Ru^{II} .

Figure 1. Single crystal X-ray structure of $[\text{Pd}([15]\text{aneS}_2\text{O}_3)_2]^{2+}$. Two views (a) and (b) with numbering scheme adopted

The synthesis of a series of mixed polythia/oxa macrocycles has been reported by Bradshaw and co-workers.^{11–13} The general procedure involves a high-dilution cyclisation of the appropriate oligoethylene glycol dichloride with ethane-1,2-dithiolate. The single-crystal X-ray structure of $[15]\text{aneS}_2\text{O}_3$ shows the S atoms lying in *exo* positions with respect to the macrocyclic ring with an S–C–C–S torsion angle of $-166.8(3)^\circ$. The two S atoms are about 4.5 Å apart and *anti* with respect to each other.¹⁴ Since the discovery of crown ethers by Pedersen^{15,16} the selectivity of these systems and their derivatives for alkali-metal cation complexation and transport has received a great deal of attention.^{17,18} Izatt *et al.*¹⁹ have demonstrated that partial substitution of O-donor atoms by sulphur changes the cation selectivity pattern. Thus, the stability of Group 1 and 2 metal complexes decreases while the affinity of the ionophores for Ag^+ and Hg^{2+} through S-binding is enhanced. A similar increased affinity for platinum-metal ions might be expected.

Few examples of transition metal complexes of mixed O/S-donor macrocycles have been reported. The complex *cis*- $[\text{PdCl}_2(\text{L})]$ (L = 1,4,10,13-tetraoxa-7,16-dithiacyclo-octadecane) incorporates Pd^{II} bound to the two thioether S-donors; however, since the S-donors are at 1,10- as opposed to 1,4-positions, the conformation of the co-ordinated ionophore is not pre-organised for guest complexation.²⁰ Our interests in the co-ordination chemistry of $[15]\text{aneS}_2\text{O}_3$ lay initially in the elucidation of structures of the resulting complexes and in the conformation(s) of the co-ordinated macrocycle around metal ions which would show highly reversible redox behaviour.

Results and Discussion

Palladium.—Treatment of PdCl_2 with one molar equivalent of $[15]\text{aneS}_2\text{O}_3$ in refluxing $\text{MeOH-H}_2\text{O}$ affords a bright yellow solution. Removal of the solvent *in vacuo* gives an

orange residue which can be recrystallised from EtOH. The fast-atom bombardment (f.a.b.) mass spectrum of the product shows a molecular-ion peak with the correct isotopic distribution at m/z 357 corresponding to $[\text{Pd}([15]\text{aneS}_2\text{O}_3) - \text{H}]^+$. The ^1H n.m.r. spectrum of the complex shows a second-order multiplet in the range δ 2.28–4.18, while the ^{13}C DEPT n.m.r. spectrum shows five distinct methylene C resonances at 71.07, 70.33, 69.38 (CH_2O), 37.64, and 35.73 p.p.m. (CH_2S). These values are shifted relative to those found for the free $[15]\text{aneS}_2\text{O}_3$ ligand (δ 72.09, 70.46, 69.23, 32.18, and 30.58 p.p.m.). The u.v.-visible spectrum of the product reveals absorption bands at $\lambda_{\text{max.}} = 394$ nm ($\epsilon_{\text{max.}} = 975$ dm³ mol⁻¹ cm⁻¹) and 262 (8 820) assigned to *d-d* and charge-transfer ($\text{S} \rightarrow \text{M}$ or $\text{Cl} \rightarrow \text{M}$) transitions respectively. The i.r. spectrum of the complex shows peaks at 340 and 320 cm⁻¹ assigned to the Pd–Cl stretching vibrations, $\nu(\text{Pd-Cl})$, of a *cis*-dichloro complex; this assignment is complicated by the possible occurrence of Pd–S stretching vibrations in the same region of the spectrum. These data, together with elemental analyses, confirm the product as *cis*- $[\text{PdCl}_2([15]\text{aneS}_2\text{O}_3)]$.

Reaction of *cis*- $[\text{PdCl}_2([15]\text{aneS}_2\text{O}_3)]$ with one, or of PdCl_2 with two molar equivalents of $[15]\text{aneS}_2\text{O}_3$ in refluxing $\text{MeOH-H}_2\text{O}$ affords a bright yellow solution. Addition of an excess of NH_4PF_6 gives a yellow precipitate which can be recrystallised from MeNO_2 . The corresponding BPh_4^- salt can be isolated by using NaBPh_4 instead of NH_4PF_6 . However, attempted recrystallisation of the BPh_4^- salt from Me_2CO , MeCN , MeNO_2 , or dimethyl sulphoxide (dmsO) resulted in its rapid decomposition to a black residue. The f.a.b. mass spectrum of the complex reveals molecular ion peaks with the correct isotopic distributions at m/z 610 and 358 corresponding to $[\text{Pd}([15]\text{aneS}_2\text{O}_3)_2]^+$ and $[\text{Pd}([15]\text{aneS}_2\text{O}_3)]^+$ respectively. The ^1H n.m.r. spectrum exhibits a series of multiplets centred at δ 3.96, 3.62, and 3.35 due to the protons of co-ordinated $[15]\text{aneS}_2\text{O}_3$. The ^{13}C DEPT n.m.r. spectrum shows resonances assigned to methylene C centres at 69.99, 68.84, 68.15 (CH_2O), and 37.11 p.p.m. (two overlapping resonances due to CH_2S) suggesting that the two macrocycles are equivalent in solution. This, combined with microanalytical and i.r., and u.v.-visible spectral data, confirms the formulation $[\text{Pd}([15]\text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ for this complex.

In order to establish the conformation of the co-ordinated macrocycles, a single-crystal X-ray structure determination of the complex was undertaken. The structure of $[\text{Pd}([15]\text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ shows [Figure 1(a) and (b)] the Pd^{II} ion occupying a crystallographic inversion centre and bound through the four thioether S-donors of two co-ordinated $[15]\text{aneS}_2\text{O}_3$ ligands, Pd–S(1) 2.314 9(10), Pd–S(4) 2.301 7(10) Å, S(1)–Pd–S(4) $89.78(4)^\circ$. As anticipated, all the O-donors are directed away from the Pd^{II} and do not interact with it. A general feature of homoleptic thioether macrocyclic co-ordination with Pd^{II} is the long-range apical interaction with fifth and sixth S-donor atoms;²¹ this clearly does not occur with the corresponding O-donors.

Platinum.—The platinum(II) complexes *cis*- $[\text{PtCl}_2([15]\text{aneS}_2\text{O}_3)]$ and $[\text{Pt}([15]\text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ have been prepared by similar routes to the Pd^{II} analogues.

The f.a.b. mass spectrum of $[\text{PtCl}_2([15]\text{aneS}_2\text{O}_3)]$ shows molecular-ion peaks with the correct isotopic distribution at m/z 483 and 447 corresponding to $[\text{Pt}^{35}\text{Cl}([15]\text{aneS}_2\text{O}_3) + \text{H}]^+$ and $[\text{Pt}^{35}([15]\text{aneS}_2\text{O}_3)]^+$ respectively. The ^1H n.m.r. spectrum shows a second-order multiplet in the range δ 2.83–4.30 assigned to the macrocyclic protons, while the ^{13}C DEPT n.m.r. spectrum shows five resonances assigned to the methylene C resonances at 70.70, 70.59, 69.60 (CH_2O), 37.85, and 35.86 p.p.m. (CH_2S). The i.r. spectrum of the complex shows peaks at 330 and 310 cm⁻¹ assigned to the Pt–Cl

Figure 2. Single crystal X-ray structure of $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ with numbering scheme adopted

stretching vibrations, $\nu(\text{Pt}-\text{Cl})$, of a *cis*-dichloro complex. Together with elemental analytical data, this confirms the product as *cis*- $[\text{PtCl}_2([\text{15}] \text{aneS}_2\text{O}_3)]$.

The f.a.b. mass spectrum of $[\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ exhibits molecular-ion peaks with the correct isotopic distribution at m/z 699 and 446 assigned to $[\text{195}\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ and $[\text{195}\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3) - \text{H}]^+$ respectively. The ^1H n.m.r. spectrum of the complex (m , δ 3.2–4.2), and the ^{13}C DEPT n.m.r. spectrum [70.17, 69.33, 69.00 (CH_2O), 37.57, and 36.86 p.p.m. (CH_2S)] are consistent with the formulation $[\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$. This, together with microanalytical, u.v.–visible and i.r. spectral data, suggests that $[\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2]^{2+}$ adopts a structure very similar to that of $[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2]^{2+}$, with square-planar co-ordination of Pt^{II} to four thioether S-donors with the O-donors directed well away from and not interacting with the metal ion.

Rhodium.—Treatment of $\text{RhCl}_3 \cdot 3\text{H}_2\text{O}$ with two molar equivalents of $[\text{15}] \text{aneS}_2\text{O}_3$ in refluxing MeOH gives a bright yellow solution. Addition of an excess of NH_4PF_6 yields an orange precipitate which can be recrystallised from MeNO_2 .

The f.a.b. mass spectrum of the complex shows molecular ion peaks with the correct isotopic distribution at m/z 677 and 642 corresponding to $[\text{103}\text{Rh}^{35}\text{Cl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ and $[\text{103}\text{Rh}^{35}\text{Cl}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ respectively. The ^1H n.m.r. spectrum of the complex shows a second-order multiplet in the range δ 2.67–4.30 due to methylene protons, and the ^{13}C DEPT n.m.r. spectrum shows five absorption methylene C resonances at 69.55, 69.40, 67.85 (CH_2O), 36.59, and 33.53 p.p.m. (CH_2S), indicating that only one isomer is present in solution. Two absorption bands at $\lambda_{\text{max.}} = 435 \text{ nm}$ ($\epsilon_{\text{max.}} = 132 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$) and 283 (32 970) are apparent in the u.v.–visible spectrum of the complex. The former is assigned to a $d-d$ transition; the magnitude of the absorption coefficient for this band is comparable to that found for *trans*- $[\text{RhCl}_2([\text{16}] \text{aneS}_4)]^{2+}$ and suggests a *trans*-dichloro formulation for the product; related *cis*-dichloro complexes tend to exhibit considerably higher absorption coefficients than their *trans* analogues.²³ The i.r. spectrum of the complex shows a single peak at 350 cm^{-1} assigned to a Rh–Cl stretching

vibration, $\nu(\text{Rh}-\text{Cl})$, confirming the assignment of the product as *trans*- $[\text{RhCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$.

Iridium.—The iridium(III) complex *trans*- $[\text{IrCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$ can be prepared by reaction of $\text{IrCl}_3 \cdot 3\text{H}_2\text{O}$ with two molar equivalents of $[\text{15}] \text{aneS}_2\text{O}_3$ in refluxing MeOH. The f.a.b. mass spectrum of the complex shows molecular-ion peaks with the correct isotopic distribution at m/z 767, 733, 696, and 444 corresponding to $[\text{193}\text{Ir}^{35}\text{Cl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$, $[\text{193}\text{Ir}^{35}\text{Cl}([\text{15}] \text{aneS}_2\text{O}_3)_2 + \text{H}]^+$, $[\text{193}\text{Ir}([\text{15}] \text{aneS}_2\text{O}_3)_2 - \text{H}]^+$, and $[\text{193}\text{Ir}([\text{15}] \text{aneS}_2\text{O}_3) - \text{H}]^+$ respectively. The ^1H (m , δ 3.3–4.2) and ^{13}C DEPT [69.68, 69.54, 67.57 (CH_2O), 35.76, and 32.60 p.p.m. (CH_2S)] n.m.r. spectra of *trans*- $[\text{IrCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ confirm the presence of one symmetrical isomer in solution. The microanalytical and i.r., and u.v.–visible spectral data are also consistent with the formulation of the isolated product as *trans*- $[\text{IrCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$.

Ruthenium.—Treatment of $[\text{RuCl}_2(\text{PPh}_3)_3]$ with two molar equivalents of $[\text{15}] \text{aneS}_2\text{O}_3$ in refluxing MeOH affords a yellow solution. Addition of an excess of NH_4PF_6 gives a yellow precipitate which can be recrystallised from CH_2Cl_2 . The f.a.b. mass spectrum of the complex shows molecular ion peaks with the correct isotopic distributions at m/z 1046, 904, 650, and 640 corresponding to $[\text{102}\text{Ru}^{35}\text{Cl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6 - 2\text{H}]^+$, $[\text{102}\text{Ru}^{35}\text{Cl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2 + \text{H}]^+$, $[\text{102}\text{Ru}^{35}\text{Cl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3) - \text{H}]^+$, and $[\text{102}\text{Ru}^{35}\text{Cl}([\text{15}] \text{aneS}_2\text{O}_3)_2 - \text{H}]^+$ respectively. The ^1H n.m.r. spectrum of this species shows a multiplet at δ 7.3–8.0 assigned to the aromatic protons of PPh_3 . Further complex multiplets are observed at δ 2.0–4.3 due to the protons of $[\text{15}] \text{aneS}_2\text{O}_3$. A stoichiometry of 1 PPh_3 :2 $[\text{15}] \text{aneS}_2\text{O}_3$ is confirmed by integration of these signals. The ^{13}C DEPT n.m.r. spectrum shows, in addition to CH resonances due to the phenyl C centres of PPh_3 , four distinct resonances at 69.36, 68.54 (two overlapping) (CH_2O), 32.04, and 30.56 p.p.m. (CH_2S) assigned to methylene C centres of $[\text{15}] \text{aneS}_2\text{O}_3$. This, together with microanalytical and i.r., and u.v. visible spectral data, suggests the formulation $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$ for the complex.

In order to determine whether this complex was a *cis* or *trans* isomer and also to establish the conformation of the co-ordinated macrocycles, a single-crystal X-ray structure determination was undertaken. The crystal structure of $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ shows (Figure 2) Ru^{II} bound octahedrally to all four thioether S-donors of two $[\text{15}] \text{aneS}_2\text{O}_3$ ligands, $\text{Ru}-\text{S}(1)$ 2.394(3), $\text{Ru}-\text{S}(1')$ 2.390(3), $\text{Ru}-\text{S}(4)$ 2.395(3), $\text{Ru}-\text{S}(4')$ 2.405(3) Å, with the Cl^- and PPh_3 ligands occupying mutually *trans* positions, $\text{Ru}-\text{Cl}(1)$ 2.458(3), $\text{Ru}-\text{P}(1)$ 2.319(3) Å. The most interesting aspect of this structure is the conformation adopted by the polyoxa linkages of the co-ordinated $[\text{15}] \text{aneS}_2\text{O}_3$ ligands. The steric bulk of the PPh_3 ligand forces the non-bonded O-donors of the two $[\text{15}] \text{aneS}_2\text{O}_3$ ligands away from PPh_3 towards the face occupied by the Cl^- ligand to form a partial cavity around Cl^- . One water solvent molecule is associated with each cation and is disordered between two mutually incompatible sites. In one of these sites the water molecule is H-bonded to an O atom of one of the $[\text{15}] \text{aneS}_2\text{O}_3$ ligands $[\text{O}(2\text{S}) \cdots \text{O}(13')]$ 3.08(4) Å].

Electrochemistry.—Cyclic voltammetry of $[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$ in MeCN (0.1 mol dm^{-3} $\text{NBu}_4^+\text{PF}_6^-$) at platinum electrodes shows two irreversible reductions at $E_{\text{pc}} = -0.75$ and $-1.20 \text{ V vs. ferrocene-ferrocenium}$ at a scan rate of 200 mV s^{-1} . No oxidative activity is observed within the range of the solvent up to +2.0 V. The redox couples for this complex vary with both temperature and scan rate and would therefore not be useful for the monitoring of secondary cation complexation.

Cyclic voltammetry of $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$ under the same conditions shows a reversible $\text{Ru}^{\text{II}}-\text{Ru}^{\text{III}}$ redox couple at $E_{\frac{1}{2}} = +0.85 \text{ V}$ vs. ferrocene-ferrocenium. However, this couple is not affected by the addition of varying concentrations of, for example, sodium ions. This is not surprising since the ruthenium(II) complex is cationic and therefore will have a large repulsive term with respect to guest-cation complexation. In addition, the polyoxa chain is not probably long enough for efficient binding of a cation. Current work is therefore aimed at synthesising neutral or anionic ruthenium(II) complexes incorporating larger ring S_2O_x ($x > 4$) donor ionophores.

Conclusion

These results confirm that the mixed thia/oxa-donor macrocycle $[\text{15}] \text{aneS}_2\text{O}_3$ co-ordinates readily to a range of platinum-group metal ions to give 1:1 and 2:1 complexes. In each case binding is through the thioether S-donors, leaving the O-donors non-interacting and directed away from the metal. Most importantly, by introducing a bulky ligand, PPh_3 , into the co-ordination sphere of the metal ion in $[\text{RuCl}(\text{PPh}_3)([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$, the conformation of the co-ordinated ionophore can be altered and, in principle, controlled and tuned. Thus, introduction of larger S_2O_n -donor ionophores and bulkier phosphine ligands would be expected to lead to better cavity definition. The presence of Cl^- or a related anion within the cavity might be an advantage under certain circumstances: if a cavity can be generated that is large enough to accommodate both Cl^- and guest cation, the attraction between the latter moieties might assist host-guest complexation.

Experimental

Infrared spectra were measured as KBr and CsI discs using a Perkin-Elmer 598 spectrometer over the range 200–4000 cm^{-1} . U.v.-visible spectra were measured in quartz cells using Perkin-Elmer Lambda 9 and Pye Unicam SP8-400 spectrophotometers. Microanalyses were performed by the Edinburgh University Chemistry Department microanalytical service. Electrochemical measurements were performed on a Bruker E310 Universal Modular Polarograph. All readings were taken using a three-electrode potentiostatic system in acetonitrile containing 0.1 mol dm^{-3} $\text{NBu}^n_4\text{PF}_6$ or $\text{NBu}^n_4\text{BF}_4$ as supporting electrolyte. Cyclic voltammetric measurements were carried out using a double platinum electrode and a Ag-AgCl reference electrode. All potentials are quoted versus ferrocene-ferrocenium. Mass spectra were run by electron impact on a Kratos MS 902 and by fast-atom bombardment on a Kratos MS 50TC spectrometer. Proton and ^{13}C DEPT n.m.r. spectra were obtained on Bruker WP80 and WP200 instruments.

The ligand $[\text{15}] \text{aneS}_2\text{O}_3$ was prepared by the method of Bradshaw *et al.*¹¹

Synthesis.— $[\text{PdCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]$. Treatment of PdCl_2 (40 mg, 0.226 mmol) with $[\text{15}] \text{aneS}_2\text{O}_3$ (57 mg, 0.226 mmol) in refluxing $\text{MeOH}-\text{H}_2\text{O}$ (35 cm^3 , 1:1 v/v) for 2 h under N_2 afforded a bright yellow solution. Removal of the solvent *in vacuo* yielded an orange residue which was recrystallised from EtOH and dried *in vacuo* (yield: 97 mg, 83%) (Found: C, 27.7; H, 4.7; Cl, 16.3. Calc. for $\text{C}_{10}\text{H}_{20}\text{Cl}_2\text{O}_3\text{PdS}_2$: C, 28.0; H, 4.7; Cl, 16.5%). Fast-atom bombardment mass spectrum [3-nitrobenzyl alcohol (noba): m/z 357; calc. for $[\text{106Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 358. N.m.r. (CD_3CN , 298 K): ^1H (200.13 MHz), δ 2.28–4.18 (m, CH_2 , 20 H); ^{13}C (50.32 MHz), δ 71.07, 70.33, 69.38 (OCH_2), 37.64, and 35.73 p.p.m. (SCH_2). U.v.-visible spectrum (MeCN):

$\lambda_{\text{max.}} = 394 \text{ nm}$ ($\epsilon_{\text{max.}} 975 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$), 262 (8 820). Infrared spectrum (KBr disc): 3 000w, 2 920m, 2 860m, 1 480w, 1 460m, 1 440w, 1 385m, 1 360m, 1 350w, 1 315m, 1 290w, 1 260w, 1 250m, 1 195w, 1 130m, 1 105vs, 1 080m, 1 060w, 1 040w, 1 020w, 990m, 940w, 910m, 900m, 870w, 840m, 820m, 790w, 780w, 615w, 560w, 520w, 360w, 340m, 320m, and 300 cm^{-1} .

$[\text{PtCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]$. Method as above but using PtCl_2 (29 mg, 0.113 mmol) and $[\text{15}] \text{aneS}_2\text{O}_3$ (30 mg, 0.113 mmol). The product was isolated as a yellow solid (yield: 33 mg, 56%) (Found: C, 22.8; H, 3.80; Cl, 14.1; S, 11.9. Calc. for $\text{C}_{10}\text{H}_{20}\text{Cl}_2\text{O}_3\text{PtS}_2$: C, 23.2; H, 3.90; Cl, 13.7, S, 12.4%). Fast-atom bombardment mass spectrum (noba): m/z 483 and 447; calc. for $[\text{195Pt}^{35}\text{Cl}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 482, $[\text{195Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 447. N.m.r. (CD_3NO_2 , 298 K): ^1H (200.13 MHz), δ 2.83–4.30 (m, CH_2 , 20 H); ^{13}C (50.32 MHz), δ 70.70, 70.59, 69.60 (OCH_2), 37.85, and 35.86 p.p.m. (SCH_2). U.v.-visible spectrum (MeCN): $\lambda_{\text{max.}} = 310 \text{ nm}$ ($\epsilon_{\text{max.}} 778 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$), 204 (10 780). Infrared spectrum (KBr disc): 3 000w, 2 980w, 2 920m, 2 860m, 1 480w, 1 460m, 1 440m, 1 385vs, 1 360m, 1 350w, 1 310m, 1 290w, 1 245m, 1 190m, 1 130vs, 1 105vs, 1 080vs, 1 040m, 1 020vs, 985m, 970m, 940m, 910m, 900m, 870w, 840m, 820m, 790w, 655w, 615w, 560w, 520m, 490w, 480w, 450w, 440w, 380w, 360w, 330m, and 310 cm^{-1} .

$[\text{Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$. Palladium dichloride (30 mg, 0.169 mmol) was added to a solution of $[\text{15}] \text{aneS}_2\text{O}_3$ (86 mg, 0.338 mmol) in $\text{MeOH}-\text{H}_2\text{O}$ (30 cm^3 , 1:1 v/v). The reaction mixture was refluxed for 2 h under N_2 to yield a bright yellow solution. Addition of an excess of NH_4PF_6 gave a yellow precipitate which was collected, recrystallised from MeNO_2 and dried *in vacuo* (yield: 110 mg, 73%) (Found: C, 26.4; H, 4.45; S, 15.2. Calc. for $\text{C}_{20}\text{H}_{40}\text{F}_{12}\text{O}_6\text{P}_2\text{PdS}_4$: C, 26.7; H, 4.45; S, 14.3%). Fast-atom bombardment mass spectrum (noba): m/z 610 and 358; calc. for $[\text{106Pd}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 610, $[\text{106Pd}([\text{15}] \text{aneS}_2\text{O}_3)]^+$ 358. N.m.r. ^1H [200.13 MHz, (CD_3)₂CO, 298 K], δ 3.96, 3.62, and 3.35 (m, CH_2 , 40 H); ^{13}C (50.32 MHz, CD_3CN , 298 K), δ 69.99, 68.84, 68.15 (OCH_2), and 37.11 p.p.m. (SCH_2). Two overlapping resonances). U.v.-visible spectrum (MeCN): $\lambda_{\text{max.}} = 305 \text{ nm}$ ($\epsilon_{\text{max.}} 32 790 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$). Infrared spectrum (KBr disc): 2 980w, 2 920m, 2 860m, 1 470m, 1 455m, 1 395m, 1 365m, 1 300m, 1 260w, 1 200w, 1 180w, 1 120vs, 1 090vs, 1 040m, 1 020w, 965w, 930m, 840vs, 780m, 740w, 555vs, and 480 cm^{-1} .

$[\text{Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2][\text{PF}_6]_2$. Method as above but using PtCl_2 (40 mg, 0.150 mmol) and $[\text{15}] \text{aneS}_2\text{O}_3$ (76 mg, 0.301 mmol). The product was isolated as a cream coloured solid (yield: 74 mg, 50%) (Found: C, 24.2; H, 4.10; S, 13.4. Calc. for $\text{C}_{20}\text{H}_{40}\text{F}_{12}\text{O}_6\text{P}_2\text{PtS}_4$: C, 24.3; H, 4.05; S, 13.0%). Fast-atom bombardment mass spectrum (noba): m/z 699 and 446; calc. for $[\text{195Pt}([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 699, $[\text{195Pt}([\text{15}] \text{aneS}_2\text{O}_3)]^+$ 447. N.m.r. (CD_3CN , 298 K): ^1H (200.13 MHz), δ 3.2–4.2 (m, CH_2 , 40 H); ^{13}C (50.32 MHz), δ 70.17, 69.33, 69.00 (OCH_2), 37.57, and 36.86 p.p.m. (SCH_2). U.v.-visible spectrum (MeCN): $\lambda_{\text{max.}} = 326 \text{ nm}$ ($\epsilon_{\text{max.}} 158 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1}$), 249 (9 150). Infrared spectrum (KBr disc): 3 020w, 2 920m, 2 860w, 1 475m, 1 455m, 1 415m, 1 400m, 1 365m, 1 350w, 1 300m, 1 260w, 1 245w, 1 195m, 1 180w, 1 120vs, 1 090m, 1 065w, 1 040m, 1 020w, 965w, 930m, 840vs, 775m, 740w, 660w, 610w, 555vs, and 480 cm^{-1} .

$[\text{RhCl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]\text{PF}_6$. The compound $\text{RhCl}_3 \cdot 3\text{H}_2\text{O}$ (30 mg, 0.114 mmol) was added to a refluxing solution of $[\text{15}] \text{aneS}_2\text{O}_3$ (57 mg, 0.228 mmol) in MeOH (30 cm^3). The reaction mixture was refluxed for 4 h under N_2 to afford a bright yellow solution. Addition of an excess of NH_4PF_6 gave an orange precipitate which was collected, recrystallised from MeNO_2 and dried *in vacuo* (yield: 85 mg, 91%) (Found: C, 28.5; H, 4.85; Cl, 8.75; S, 16.6. Calc. for $\text{C}_{20}\text{H}_{40}\text{Cl}_2\text{F}_6\text{O}_6\text{PRhS}_4$: C, 29.2; H, 4.90; Cl, 8.60; S, 15.6%). Fast-atom bombardment mass spectrum (noba): m/z 677 and 642; calc. for $[\text{103Rh}^{35}\text{Cl}_2([\text{15}] \text{aneS}_2\text{O}_3)_2]^+$ 677, $[\text{103Rh}^{35}\text{Cl}([\text{15}] \text{aneS}_2\text{O}_3)]^+$ 642.

[RuCl(PPh₃)([15]aneS₂O₃)₂][PF₆]. Treatment of [RuCl₂(PPh₃)₃] (100 mg, 0.104 mmol) with [15]aneS₂O₃ (53 mg, 0.208 mmol) in refluxing MeOH (30 cm³) for 2 h under N₂ affords a yellow solution. Addition of an excess of NH₄PF₆ gave a yellow product which was collected and recrystallised from CH₂Cl₂ (yield: 100 mg, 92%) (Found: C, 44.1; H, 5.35. Calc. for C₃₈H₅₅ClF₆O₆P₂RuS₄: C, 44.7; H, 5.45%). Fast-atom bombardment mass spectrum (noba): *m/z* 1 046, 904, 650, and 640; calc. for [¹⁰²Ru³⁵Cl(PPh₃)([15]aneS₂O₃)₂]⁺ 1 048, [¹⁰²Ru³⁵Cl(PPh₃)([15]aneS₂O₃)₂]⁺ 903, [¹⁰²Ru³⁵Cl(PPh₃)([15]aneS₂O₃)]⁺ 651, [¹⁰²Ru³⁵Cl([15]aneS₂O₃)₂]⁺ 641. N.m.r.: ¹H (80.13 MHz, CD₃NO₂, 298 K), δ 7.3–8.0 (m, Ph, 15 H) and 2.0–4.3 (m, CH₂, 40 H); ¹³C [50.32 MHz, (CD₃)₂CO, 298 K], δ 134.01 (d), 131.06 (d), 129.67 (d), 127.29 (d) (C of Ph rings), 69.36, 68.54 (two overlapping) (OCH₂), 32.04, and 30.56 p.p.m. (SCH₂). Infrared spectrum (KBr disc): 3 040w, 2 920m, 2 860m, 1 585w, 1 570w, 1 480m, 1 455w, 1 430m, 1 410m, 1 360m, 1 290m, 1 190w, 1 130m, 1 110m, 1 090m, 1 000w, 840vs, 750m, 700vs, 555vs, 530vs, 515m, 505w, and 465w cm^{–1}.

X-Ray Structure Determination of [Pd([15]aneS₂O₃)₂][PF₆]₂.—An orange plate (1.0 × 0.10 × 0.75 mm) suitable for X-ray analysis was obtained by vapour-diffusion of diethyl ether into a solution of the complex in MeCN.

Crystal data. C₂₀H₄₀O₆PdS₄·2PF₆, *M* = 901.0, monoclinic, space group *P*₂₁/*c* with *a* = 10.394(4), *b* = 14.003(4), *c* = 11.675(5) Å, β = 104.22(3)°, *U* = 1 647 Å³ [from 2θ values of 25 reflections measured at ±ω (36 ≤ 2θ ≤ 38°, λ = 0.710 73 Å, *T* = 298 K)], *D*_c = 1.816 g cm^{–3}, *Z* = 2, *F*(000) = 912, μ(Mo-*K*_α) = 9.95 cm^{–1}.

Data collection and processing. Stoë STADI-4 four-circle diffractometer, graphite monochromated Mo-*K*_α radiation, ω–2θ scans, 2 808 unique reflections measured (2θ_{max} = 45°, *h* –12 to 12, *k* 0–16, *l* 0–12), initial absorption corrections (min. 0.985, max. 1.015) made using ψ scans, giving 2 402 with *F* ≥ 6σ(*F*). No significant crystal decay or movement was observed.

Structure analysis and refinement. Intensity statistics strongly implied the location of the Pd atom at (½, ½, ½). Using this

information, DIRDIF²⁴ located all other non-H atoms. At isotropic convergence, final corrections (min. 0.875, max. 1.290) for absorption were made using DIFABS.²⁵ Anisotropic thermal parameters were refined for all non-H atoms, H atoms were included in fixed, calculated positions.²⁶ The weighting scheme $w^{-1} = \sigma^2(F) + 0.000\ 187F^2$ gave satisfactory agreement analyses. At convergence, R , $R' = 0.0394$, 0.0537 respectively for 205 parameters, $S = 1.195$. The maximum and minimum residues in the final ΔF syntheses were $+0.67$ and $-0.51\ \text{e}\ \text{\AA}^{-3}$ respectively. Bond lengths, angles and torsion angles are given in Table 1 and fractional atomic co-ordinates in Table 2.

X-Ray Structure Determination of [RuCl(PPh₃)([15]aneS₂O₃)₂]PF₆·H₂O.—A yellow lath ($0.08 \times 0.23 \times 0.38\ \text{mm}$) suitable for X-ray analysis was obtained by recrystallisation of the complex from CH₂Cl₂–EtOH.

Crystal data. C₃₈H₅₅ClO₆PRuS₄·PF₆·H₂O, $M = 1\ 066.5$, orthorhombic, space group $Pbcn$ with $a = 19.252\ 6(14)$, $b = 25.968(3)$, $c = 18.903\ 3(23)\ \text{\AA}$, $U = 9\ 451\ \text{\AA}^3$, $D_c = 1.499\ \text{g}\ \text{cm}^{-3}$, $Z = 8$; $F(000) = 4\ 400$, $\mu(\text{Mo-K}\alpha) = 6.84\ \text{cm}^{-1}$.

Data collection and processing. STADI-4 diffractometer, graphite-monochromated Mo-K α radiation, ω —20 scans, 7 634 reflections measured ($2\theta_{\text{max}} = 45^\circ$, $h\ 0$ —20, $k\ 0$ —27, $l\ 0$ —20) giving 3 127 with $F \geq 6\sigma(F)$. No significant crystal decay, no absorption correction.

Structure analysis and refinement. The Ru atom was located by a Patterson synthesis. The structure was developed by iterative rounds of least-squares refinement and difference Fourier synthesis.²⁴ Two half-occupied, mutually incompatible water molecules were found to be H-bonded to each complex cation. The phenyl rings of the PPh₃ ligand were refined as idealised hexagons. Anisotropic thermal parameters were refined for Ru, Cl, P, S, F, and all fully occupied O atoms. H atoms were included in fixed, calculated positions.²⁴ The weighting scheme $w^{-1} = \sigma^2(F) + 0.000\ 793F^2$ gave satisfactory agreement analyses. At convergence, R , $R' = 0.0603$, 0.0774 respectively for 305 parameters, $S = 1.111$. The maximum and minimum residues in the final ΔF syntheses were $+0.60$ and $-0.46\ \text{e}\ \text{\AA}^{-3}$ respectively. Illustrations were prepared using ORTEP,²⁷ molecular geometry calculations utilised CALC,²⁸

* Carbon atoms of the phenyl groups of PPh_3 are indicated by R, O atoms of the solvent water by S.

and scattering factor data were taken from ref. 29. Bond lengths, angles, and torsion angles are given in Table 3 and fractional co-ordinates are given in Table 4.

Additional material available from the Cambridge Crystallographic Data Centre comprises H-atom co-ordinates, thermal parameters, and remaining bond lengths and angles.

Acknowledgements

We thank the S.E.R.C. for support and Johnson Matthey plc for generous loans of platinum metal salts.
