The range of imides trans-[MoCl(NCHR¹R²)(dppe)₂] + made from the nitride trans-[MoCl(N)(dppe)₂] (dppe = Ph₂PCH₂CH₂PPh₂, R¹ = H or organic group, R² = organic group) has been extended; deprotonation of the imide group at the α -carbon gives reactive alkenylamides which have nitrogen ylide character {Mo \equiv N²-C⁻HR} and these are attacked by electrophiles. Stepwise C₁ homologation of a methylimide to ethyl- and isopropyl-imides can be achieved by successive deprotonation and methylation steps. The crystal structure of the alkenylamide trans-[MoCl(NCHCO₂Me)(dppe)₂] has been determined, as has that of the imide produced directly from it by C-methylation, trans-[MoCl{NCH(Me)CO₂Me}(dppe)₂] +. Deprotonation at the α -carbon of an allylimide complex gives a species which is regioselectively and stereospecifically attacked by electrophiles at the γ -carbon; when the electrophile is the proton the overall reaction corresponds to a 1,3-prototropic rearrangement of the allylimide to the *E*-methylvinylimide. Electroreduction of imides in the presence of a source of protons releases the free amine; in this way esters of the amino acids glycine and DL-alanine have been synthesised. Two protons can be removed by base from imides with electron-withdrawing ester substituents and free cyanoformate esters are released from the metal centre by substitution with dinitrogen or CO.

Transition-metal nitrides are potentially useful reagents for introducing nitrogen functions into organic molecules. Complexes of the general type trans-[MX(N)(L-L)₂] [M = Mo or W; X = halide; L-L = 1,2-bis(di-aryl- or -alkyl-phosphino)ethane] are particularly attractive in this context because the nitride ligand is nucleophilic and the square-planar {M(L-L)₂} assembly is robust. Such nitrides can be prepared from dinitrogen complexes of the type trans-[M(N₂)₂(L-L)₂] either by cleavage of an N-N bond 2 or by reaction with trimethylsilyl azide. 3

This paper focuses on the chemistry of the $\{Mo \equiv N^+ - CH_2R\}$ group in complexes formed by alkylation of one such nitride, $trans-[MoCl(N)(dppe)_2]$ (dppe = $Ph_2PCH_2CH_2PPh_2$) by RCH₂I (R = H or organic substituent).³ Pathways for the of the methylimide conversion group in [MoCl(NMe)(dppe)₂]⁺ into ligated cyanide, aminocarbyne, isocyanate, isothiocyanate, isoselenocyanate groups or its release as methylamine have been described 4 and a preliminary account of the synthesis of glycine and DL-alanine methyl esters from trans-[MoCl(NCH₂CO₂Me)(dppe)₂] + 1 has been given.¹ A mechanistic study suggested that two α-protons can be removed from 1 when this complex is treated with the methoxide ion.

Results and Discussion

Synthesis of Organoimides from trans- $[MoCl(N)(dppe)_2]$.—Primary alkyl iodides RCH_2I (R = H, Me, Prⁿ, MeOCO,

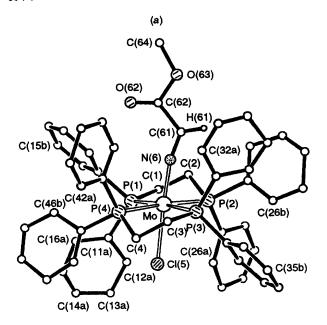

EtOCO or CH₂=CH) react with *trans*-[MoCl(N)(dppe)₂] in tetrahydrofuran (thf) to give cations *trans*-[MoCl(NCH₂R)-(dppe)₂]⁺, isolable as iodide or other salts. Data for all new compounds are given in the Experimental section. Under similar conditions, the secondary and tertiary iodides Me₂CHI and Me₃CI do not react to a measurable extent, but *trans*-[MoCl(NCHMe₂)(dppe)₂]⁺ can be synthesised indirectly from the ethylimide *trans*-[MoCl(NEt)(dppe)₂]⁺, see below.

Formation and Alkylation of Nitrogen Ylides trans-[MoCl-(NCHR)(dppe)₂]: Structures of trans-[MoCl(NCHCO₂Me)-(dppe)2] and its C-Methylated Derivative trans-[MoCl{NCH- $(Me)CO_2Me_3(dppe)_2$.—Triethylamine removes a proton from the cation *trans*- $[MoCl(NCH_2CO_2Me)(dppe)_2]$ ⁺ 1 to give the neutral alkenylamide trans-[MoCl(NCHCO₂Me)-(dppe)₂] 2, the structure of which has been determined by X-ray crystallography, Fig. 1. Complex 2 has incipient carbanion character and reacts with methyl iodide at the acarbon to form a C-C bond. The structure of the methylated product trans-[MoCl(NCHMeCO₂Me)(dppe)₂] + 3 has also been confirmed by X-ray crystallography on two forms of the iodide salt (3a and 3b, see Experimental section) and the structure of one is also shown in Fig. 1. The dimensions of the imide 3 are generally similar to those found for trans- $[MoCl(NMe)(dppe)_2]^+$, for example Mo-N in 3a is 1.742(6) Å and that in the methylimide is 1.733(5) Å.⁶

The principal changes in the molecular dimensions of complex 2 upon C-methylation to produce 3 are as follows. The Mo-N shortens in accord with an increase in multiple-bond character whereas, the N-C bond lengthens consistent with a decrease in C=N double-bond character. The Mo-P bond lengthens as Mo to P back bonding is diminished by the overall

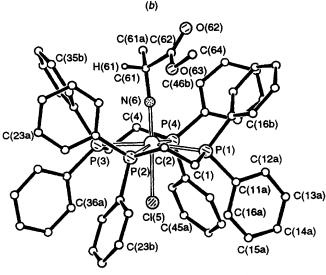

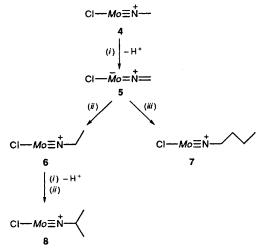

Fig. 1 (a) View of the molecule trans-[MoCl(NCHCO₂Me)(dppe)₂] 2. (b) View of the cation trans-[MoCl{NCH(Me)CO₂Me}(dppe)₂] + of 3a; that of 3b is similar but has disorder in the imide ligand (see Experimental section). The atom numbering schemes are indicated

positive charge, whereas the Mo-Cl bond length is decreased. Similar changes have been documented for related systems. A further difference between 2 and 3 is the alignment of the nitrogen ligands: in 2 the amide plane lies between the two phosphine ligands whereas in 3 (a or b) the ester group lies over one of the P-C-C-P linkages, i.e. perpendicular to the arrangement in 2. The essentially planar conformation of the nitrogen ligand in 2, together with the disposition of the substituent groups with respect to the dppe coligands, is discussed in the context of regionselective and stereospecific reactions described below. X-Ray structural data are given in Tables 1-4 and the syntheses of 1-3 are described in the Experimental section.

Removal of a proton from trans-[MoCl(NMe)(dppe)₂] ⁺ 4 requires a strong base. In earlier work it has been shown that treatment of 4 in thf with K[OBu'] gives trans-[MoCl(NCH₂)-(dppe)₂] 5.⁴ Although 5 has an extensive oxidation chemistry.⁴ its reactions with carbon electrophiles has not been explored hitherto. Methyl iodide methylates 5 giving trans-[MoCl(NEt)(dppe)₂] ⁺ 6; analogously, with n-propyl iodide, trans-[MoCl(NBu)(dppe)₂] ⁺ 7 is formed, Scheme 1.

Scheme 1 Conversion of a methylimide to into ethyl-, butyl- and isopropyl-imides; *Mo* represents *trans*-{Mo(dppe)₂}. (i) Base; (ii) MeI; (iii) PrⁿI

The ethyl imide trans-[MoCl(NEt)(dppe)₂] + 6 also reacts with K[OBu'] to generate a reactive ylide. The product trans-[MoCl(NCHMe)(dppe)₂] proved too sensitive to isolate in the solid state in a pure form but the following evidence shows that it is generated essentially quantitatively in thf solution. Addition of K[OBu'] to a solution of 0.2 mol dm-3 [NBu₄][BF₄]-thf containing trans-[MoCl(NEt)(dppe)₂]⁺ resulted in the disappearance of the voltammetric reduction peak for the parent cation and the appearance of a single new process corresponding to the oxidation of the deprotonated product. The peak oxidation potential ${}^{ox}E_p$ of this product was near to that observed for closely related 5, Table 5. ${}^{31}P-\{{}^{1}H\}$ NMR spectroscopy in thf showed the disappearance of the resonance of trans-[MoCl(NEt)(dppe)₂] + on addition of the base and the appearance of a single new resonance. The chemical shift of the product is close to that of the methyleneamide analogue, Table 5. Finally, deprotonation of trans-[MoCl(NEt)(dppe)₂] followed by addition of MeI 'trapped' the ylide as the isopropylimide cation trans-[MoCl(NCHMe₂)(dppe)₂] + 8, which was isolated and characterised as the iodide salt, Scheme 1.

Whereas the ethyl- or butyl-imide complexes 6 and 7 can be prepared directly from the parent nitride by reaction with the appropriate *n*-alkyl iodide, the isopropyl derivative 8 is not accessible by this route.

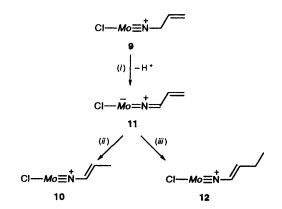

Cyclic voltammetric data show that complex 8 is also deprotonated by K[OBu'] in the to give a nitrogen ylide, Table 5, but attempts to extend the C₁ homologation to produce the tert-butylimide derivative failed. Bulky ligands do not coordinate to {M(dppe)₂} sites because of steric repulsion by the closely packed phenyl rings of the dppe ligands. The inability to form the tert-butyl derivative is presumably also a consequence of steric constraints.

1,3-Prototropic Rearrangement of an Allyl- to a Methylvinylimide Ligand; Regioselective and Stereospecific Attack by Electrophiles at the γ-Carbon of trans- [MoCl-(N=CHCH=CH₂)(dppe)₂].—Deprotonation of the allylimide trans-[MoCl(NCH₂CH=CH₂)(dppe)₂]⁺ 9 by K[OBu¹] in thf followed by reprotonation with HBF₄ does not lead to regeneration of the parent cation but to the formation of the methylvinylimide, trans-[MoCl(NCH=CHMe)(dppe)₂]⁺ 10 by attack at the γ-carbon. The overall reaction can be viewed as a 1,3-prototropic shift which proceeds via trans-[MoCl(N=CH=CH₂))(dppe)₂] 11, Table 5. Treatment of 9 in thf with HBF₄ alone does not result in rearrangement.

Table 1 Final atomic coordinates (fractional × 10⁴) for trans-[MoCl(NCHCO₂Me)(dppe)₂]-CH₂Cl₂ 2 with estimated standard deviations (e.s.d.s)

Scheme 2 Conversion of an allylimide to methyl- or ethyl-vinylimides; Mo represents trans-{Mo(dppe)₂}. (i) Base; (ii) H⁺; (iii) MeI

Compounds 9 and 10 are easily distinguished electrochemically. Cyclic voltammetry shows that the vinyl product resulting from deprotonation/reprotonation of 9 is some 300 mV easier to reduce than is the parent allylimide and that its reduction is partially reversible at room temperature: reversibility in the reduction of 9 is only observed at temperatures below $-10\,^{\circ}\text{C}$. Presumably the lower energy of the lowest unoccupied molecular orbital (LUMO) of 10 and the greater stability of the anion is a consequence of metal-ligand π^* character delocalised across the MoNCC framework. The voltammetry

shows that the regioselectivity is greater than 90%, Scheme 2 and Fig. 2.

The proton NMR spectrum of the product trans-[MoCl(NCH=CHMe)}(dppe)₂] + 10 shows that the E isomer is exclusively formed. The coupling constant $^3J(CH=CH)$ is 15 Hz which is characteristic of protons in the E configuration. Confirmation of this stereochemistry was obtained by simulations of the ethylenic region of the 1H NMR spectrum. $^3J(CH=CH)$ for Z isomers are typically in the region of 8 Hz; taking this value gives a calculated spectrum for the β proton which is essentially a quintet rather than the sextuplet actually observed. Iterative simulation gives a resonance pattern in excellent agreement with the experimental spectrum with $^3J(CH=CH) = 15$ Hz, Fig. 3.

The reaction of complex 11 with MeI similarly produces the ethylvinylimide cation trans-[MoCl(NCH=CHEt)](dppe)₂]⁺ 12 by electrophilic attack at the γ -carbon. Again cyclic voltammetry and ¹H NMR spectroscopy show that the reaction is regiospecific and that the imide ligand also adopts the E configuration, Scheme 2. Electrophilic attack at either the α - or γ -carbons is consistent with carbanion character contributing to the resonance structure of 11, as represented by the canonical forms in Scheme 3. As discussed below, the regioselectivity and stereospecificity of the reactions are closely linked: stereospecificity will be considered first.

The formation of the E isomers of the alkylvinylimides 10 and 12 must originate from steric constraints imposed by the dppe ligands. Maximisation of π -orbital interactions within the

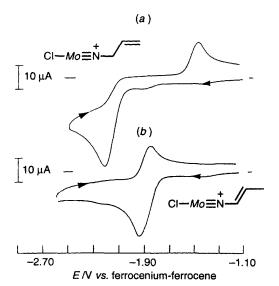

Fig. 2 Cyclic voltammograms of (a) the allyl complex 9 and (b) the methylvinyl product 10. Recorded in thf-0.2 mol dm⁻³ [NBu₄][BF₄] at a vitreous carbon electrode, scan rate 100 mV s⁻¹. At -25 °C the reduction of 9 appears partially reversible. Note trace of 10 in voltammogram (a) and 9 in (b)

precursor complex 11 requires planarity of the {Mo-N= CHCH=CH₂} moiety, just as is observed for the {Mo-N=CHC= O(OMe) group in 2, Fig. 1. If we assume that the dppe ligands in 11 are arranged about the Mo in a similar fashion to that in 2, then two planar configurations of the amide ligand in 11 with respect to these coligands can be envisaged; these are represented in Scheme 4 (a and b). The Z arrangement directs the larger $\{CH_2\}$ substituent group on the β -carbon towards the phenyl groups of the dppe ligand, Scheme 4(a). In contrast, adoption of the E configuration places this group in the exo position with the smaller H substituent on the β-carbon now directed towards the phenyl groups, Scheme 4(b). With the latter arrangement steric repulsions are clearly minimised. Electrophilic attack on the γ-carbon of 11 with the alkenylamide group locked in the E configuration would give exclusively the E product, as is experimentally observed, Scheme 2.

Some indication of the importance of such steric interactions in determining the orientation of substituent groups is evident from the crystal structure of complex 2. The O atom on the β -carbon, O(62), is directed towards the phenyl ligands, whereas the larger MeO group occupies the exo position and is well clear of phenyl-group contacts. Note that even with this arrangement steric repulsion appears to result in some tilting of the rigid, planar NCHCO₂Me group away from the phenyl rings, Fig. 1(a). The crystal structure of trans-[MoCl(NCHMeCO₂Me)-

(dppe)₂]⁺ 3a shows that both O and OMe substituents on the β -carbon are free to orientate away from the phenyl rings, the α -carbon is saturated and the electronic restriction for π -delocalisation across the MoNCCO framework is lifted, Fig. 1(b).

That C-H or C-C bond formation occurs regioselectively at the γ -carbon can be explained in the following way. The two dppe ligands hinder lateral access to the α -carbon of the alkenylamide ligand of complex 11: in the favoured E configuration, the exo γ -carbon is the 'first in line' of the two nucleophilic carbon centres with respect to attack by an electrophile from a nominally axial direction. Attack at the exo-carbon commits the system to irreversible formation of the alkylvinylimide product 10 or 12.

The regioselective and stereospecific course of the above reactions shows some parallel with electrophilic attack on certain alkenyldiazenide complexes of tungsten reported by Hidai and co-workers. For example, trans-[WF{N=N-C(Me)=CH₂}(dppe)₂] reacts with methyl iodide at the exomethylene group to give the E-diazoalkane product trans-[WF(NN=CMeEt)(dppe)₂]⁺ (cf. formation of the E isomer by γ -carbon methylation of 11). Notably, methylation at the β -nitrogen (corresponding to the α -carbon in 11) does not take place, although this type of reaction readily occurs with closely related alkyldiazenide complexes. As far as we are aware, 1,3-prototropic shifts involving the interconversion of alkenylhydrazide and diazoalkane groups, e.g. NNH(CH=CH₂) \longleftrightarrow NN=CHMe, have yet to be observed.

Formation of Cyanoformate Esters from trans- $[MoX(NCH_2CO_2R')(dppe)_2]^+$ (X = Cl or I, R' = Me or Et).—Mechanistic studies of the deprotonation of trans- $[MoCl(NCH_2CO_2Me)(dppe)_2]^+$ 1 showed that the electron-withdrawing ester group allowed the successive removal of two protons from the α -carbon by methoxide, thereby generating an anion possessing a co-ordinated cyanoformate ester group, Scheme 5.5 Halide or nitrile ligands are known to be readily replaced by CO or N₂ at $\{Mo^0(dppe)_2\}$ centres. This suggested that it might be possible to release cyanoformate esters and form stable molybdenum(0) complexes via substitution of the axial ligands in trans- $[MoX(NC-CO_2R')(dppe)_2]^-$.

The complex trans-[MoCl(NCCO₂Et)(dppe)₂] was generated in thf by treatment of 2 with an excess of K[OBu^t] and the solution was stirred under an atmosphere of carbon monoxide for ca. 40 h. Work-up afforded [Mo(CO)₂(dppe)₂] (cis and trans isomers) and the free ester N=C-CO₂Et. The reaction of CO with the iodide trans-[MoI(NCCO₂Et)-(dppe)₂] gave the same products in somewhat better yield (ca. 80% yield of each). The corresponding reaction under molecular nitrogen gave trans-[Mo(N₂)₂(dppe)₂] together with the free ester both in a yield of 60%. The isolated metal products were identified by infrared spectroscopy and cyclic voltammetry; N=C-CO₂Et was identified by infrared spectroscopy and HPLC. These results are summarised by Scheme 5 and details of the reactions are given in the Experimental section.

It seems likely that the cyanoformate ester and the molybdenum(0) products are formed by a sequence involving dissociative loss of the halide, binding of the π -acid ligand, dissociative loss of the cyanoformate ester and binding of the second π -acid ligand, as outlined in Scheme 5. Dissociative

$$X-Mo = N$$

Scheme 5 Release of ethyl cyanoformate from an imide ester; *Mo* represents *trans*-{Mo(dppe)₂}, (i) NEt₃; (ii) GBu^t, (iii) N₂; (iv) CO

substitution reactions are well established at $\{Mo^{0}(dppe)_{2}\}\$ centres and halides tend to be more labile than nitrile ligands. ¹⁰ We have prepared *trans*- $[Mo(N_{2})(NCCO_{2}Et)(dppe)_{2}]$ and find that it reacts with dinitrogen at 1 atm (*ca.* 10⁵ Pa) in thf to give *trans*- $[Mo(N_{2})_{2}(dppe)_{2}]$, as is consistent with this pathway.

Although [MoCl(NCCO₂Me)(dppe)₂] protonates to regenerate the parent cation 1, its reaction with MeI only gives the monomethylated product. Again, the steric demands of the dppe ligands must prevent formation of a tertiary α -carbon centre.

Formation of Glycine and DL-Alanine Esters by Electro-reductive Cleavage of Mo-N Bonds in trans-[MoCl-(NCHRCO₂Me)(dppe)₂]⁺, (R = H or Me).—In earlier work it was shown that electrochemical reduction of the methylimide cation trans-[MoCl(NMe)(dppe)₂]⁺ under dinitrogen in the presence of phenol gives methylamine and trans-[Mo(N₂)₂-(dppe)₂] in an overall four-electron process. ¹¹ We thought it should be possible to release glycine or DL-alanine methyl esters by an analogous reduction of trans-[MoCl(NCHRCO₂Me)-(dppe)₂]⁺.

Controlled-potential reductions of *trans*-[MoCl(NCH₂-CO₂Me)(dppe)₂]⁺ 1 were carried out at -2.3 V *versus* ferrocenium–ferrocene in thf–0.2 mol dm⁻³ [NBu₄][BF₄] at a mercury-pool cathode in the presence of phenol under molecular nitrogen. Coulometry showed that the electrode reaction consumed 1.3 F mol⁻¹ of the starting material; cyclic voltammetry on the catholyte at the end of electrolysis revealed the formation of two metal products, *trans*-[Mo(N₂)₂(dppe)₂] and *trans*-[MoCl(NCHCO₂Me)(dppe)₂] 2 in yields of *ca.* 30 and *ca.* 60% respectively. Thin-layer chromatography and spectrophotometry confirmed the formation of the glycine ester in *ca.* 40% yield. The stoichiometry and charge consumption are broadly consistent with an overall reduction corresponding to that shown by Scheme 6 whereby the formation of 2 is explained by the sacrificial consumption of 1 as the proton source.

We sought to increase the yield of the amino acid ester by using a stronger acid than phenol, so as to circumvent the unproductive deprotonation step. Controlled-potential electrolysis of *trans*-[MoCl(NCHRCO₂Me)(dppe)₂]⁺ in the presence of acetic acid led to the formation of glycine (R = H) or DL-alanine (R = Me) esters in yields of 70 and 80% respectively. The electrolysis involves a coupled dihydrogen evolution cycle which is catalysed by the metal product formed on release of the amino acid ester, Scheme 7.

Cyclic voltammetry of trans-[MoCl(NCHRCO₂Me)-(dppe)₂]⁺ in the presence of acetic acid shows the formation of the monohydride complex [MoH(η^2 -O₂CMe)(dppe)₂] under dinitrogen or argon, Fig. 4. Under electrolysis conditions, monohydride formed at the electrode diffuses into the bulk solution where it is slowly protonated to give a dihydride cation

Scheme 6 Release of glycine methyl ester from complex 1 by electrolysis under dinitrogen; the sacrificial consumption of 1 provides the source of protons; Mo represents trans-{Mo(dppe)₂}

Scheme 7 Release of amino acid esters from imide esters by electrolysis in the presence of acetic acid. The species in brackets are postulated intermediates detected in related systems, see refs. 10 and 11. Mo represents trans-{Mo(dppe)₂}; R = Me or H

[MoH₂(η^2 -O₂CMe)(dppe)₂]⁺. The reduction of the dihydride occurs at a potential positive of that for the parent imide cation and an independent study has shown that this leads to the formation of a thermally unstable trihydride [MoH₃(η^1 -O₂C-Me)(dppe)₂]. Loss of H₂ from the trihydride regenerates [MoH(η^2 -O₂CMe)(dppe)₂] which sustains the catalytic cycle.

[MoH(η²-O₂CMe)(dppe)₂] which sustains the catalytic cycle. Based upon this and earlier work¹¹ we suggest that the amino acid esters and metal products are formed by the pathway outlined in Scheme 7. Notably the monohydride is generated when either trans-[MoCl₂(dppe)₂], trans-[MoCl(NH)(dppe)₂] or trans-[MoCl(O)(dppe)₂] are reduced in the presence of acetic acid.

Cyclic voltammetry of the other organoimides reported herein shows that each undergoes reduction at a vitreous carbon electrode in thf-0.2 mol dm ³ [NBu₄][BF₄] and that their conjugate organoamides undergo facile oxidation, Table 5. The nature of the products formed by controlled-potential reduction or oxidation of these compounds is currently being investigated.

Conclusion

The reactions described herein begin to illustrate how a nucleophilic molybdenum nitride can be used to convert organic iodides into organonitrogen products. Changing the metal or the diphosphine coligands could extend the scope of such reactions. For example, increasing the nucleophilicity of

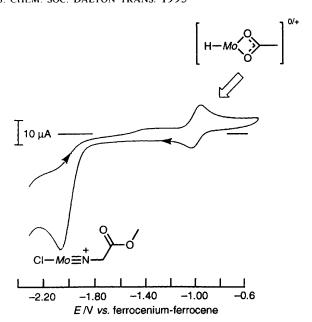

Fig. 4 Cyclic voltammogram of the imide complex 1 showing generation of the hydride upon holding the potential at $-2.17\,V$ for $20\,s$ in the presence of acetic acid. Recorded in thf–0.2 mol dm $^{-3}$ [NBu₄][BF₄] at a vitreous carbon electrode, scan rate 100 m V s $^{-1}$

the ylide might allow carboxylation with CO_2 ; less sterically demanding diphosphine ligands might permit bulkier substituents to be introduced at the primary α -carbon and/or its conversion to a tertiary carbon centre.

Rather than behaving as merely 'spectator' ligands, it is becoming apparent that simple dppe coligands can exert stereochemical control over the reaction course of a group bound in an axial position: asymmetric diphosphine coligands might provide a route to chiral products and this is being investigated.

Experimental

All manipulations were carried under an inert atmosphere of dinitrogen or argon using Schlenk techniques. Solvents were freshly distilled from appropriate drying agents under dinitrogen. Alkyl iodides are best used freshly distilled under vacuum in the dark from K_2CO_3 . The complexes trans- $[MoX(N)(dppe)_2]$ (X = Cl or Br) were prepared by the method of Chatt and Dilworth.³

The NMR measurements were made on a JEOL GSX MHz instrument, chemical shifts being given in ppm. Infrared spectra were recorded on a Bio-Rad 3240 FTS-7 FTIR spectrometer. Spectrophotometric measurements were performed on a Perkin-Elmer Lamda 5 spectrophotometer. The HPLC analyses were made using a JASCO 880-PU pump and a Shimadzu SPD-SA UV detector. Mass spectra (FAB and electron impact, EI) were obtained using an Analytical Fison Instruments Auto Spec VG spectrometer; FAB spectra were generated using 3-nitrobenzyl alcohol as the matrix.

Cyclic voltammetric and controlled-potential electrolysis experiments were carried out using a Hi-Tek DT 2101 potentiostat interfaced with a Hi-Tek PPR1 waveform generator and data were recorded on a Philips PM 8041 X-Y recorder. Coulometric measurements were made using an electronic integrator supplied by Southampton University. Three electrode—two compartment cells equipped with vitreous carbon-disc or platinum-wire working electrodes, a tungstenwire secondary electrode and a silver-wire pseudo-reference electrode or a calomel reference electrode were employed for cyclic voltammetric measurements. The concentrations of the complexes were typically 1–2 mmol dm⁻³ and 0.2 mol dm⁻³ [NBu₄][BF₄] was used as the supporting electrolyte in thf or

other solvents. Controlled-potential electrolyses were made in an H-type cell with a three-electrode-three compartment configuration as detailed below.

Microanalyses (C, H, N) were made in house or by the Department of Chemistry, University of Surrey.

trans-[MoCl(NEt)(dppe)2][BPh4] 6.—The complex trans-[MoCl(N)(dppe)₂] (1.1 g, 1.2 mmol) was dissolved in thf (70 cm³) at room temperature. An excess of EtI (1 cm³) was added and the reaction mixture stirred overnight. During this time the solution changed from yellow to reddish pink and some pink solid precipitated. The solution was reduced in volume to ca. 5 cm³ and the pink solid filtered off. The solid was extracted twice with CH₂Cl₂. The combined extract was evaporated to dryness and the solid washed with cold thf $(3 \times 5 \text{ cm}^3)$ then Et₂O (2 × 5 cm³) and dried in vacuo giving trans-[MoCl(NEt)-(dppe)₂]I (0.91 g, 70% yield). The product was dissolved in MeOH (30 cm³) and an excess of NaBPh₄ was added to the stirred solution. Bright pink trans-[MoCl(NEt)(dppe)₂][BPh₄] precipitated. This was filtered off, washed with MeOH (3 × ca. 3 cm³), Et₂O (3 × ca. 3 cm³) and dried in vacuo. FAB mass spectrum m/z 972 (M^+) [Found (Calc. for $C_{78}H_{73}BClMoNP_4$): 71.8 (72.6); H, 5.70 (5.70); N, 1.2 (1.1)%]. NMR (CD_2Cl_2): ¹H (relative to SiMe₄, 270.16 MHz), $\delta = 2.04$ (t, 3 H, CH₃), 1.855 (m, 2 H, NCH₂), 2.6–2.9 (two br m, 8 H, PCH₂CH₂P) and 6.8-7.5 (m, 60 H, PPh and BPh); ³¹P-{¹H} (relative to trimethyl phosphite, 109.25 MHz), δ –97.0.

trans-[MoCl(NCH₂CH=CH₂)(dppe)₂][PF₆] 9.—Pink trans-[MoCl(NCH₂CH=CH₂)(dppe)₂]I was synthesised in 80% yield from the nitride and allyl iodide by the procedure described above. It was converted into the [PF₆] salt with Tl[PF₆] (**CAUTION**: poison) or to the [BPh₄] salt as before. FAB mass spectrum: m/z 984 (M^+) [Found (Calc. for C₅₅H₅₃ClF₆MoNP₅): C, 58.1 (58.6); H 4.9 (4.7); N 1.3 (1.2)%]. NMR (CD₂Cl₂) for [BPh₄] salt: ¹H (270.16 MHz), δ 2.35 (d, 2 H, NCH₂), 2.6–2.9 (two br m, 8 H, PCH₂CH₂P), 4.24 (m, 2 H, CH₂=CH), 4.62 (m, 1 H, CH₂=CHCH₂) and 6.8–7.5 (m, 60 H, PPh and BPh); ³¹P-{¹H} (109.25 MHz), δ –96.8 (s).

trans-[MoCl(NCH₂CO₂Me)(dppe)₂]l 1.—The complex trans-[MoCl(N)(dppe)₂] (0.45 g, 0.48 mmol) was dissolved in thf (30 cm³) at room temperature, ICH₂CO₂Me (0.27 cm³, 0.75 mmol) was added and the reaction mixture stirred overnight. A violet solid precipitated which was filtered off, washed with thf (2 × 5 cm³) then Et₂O (2 × 5 cm³) and dried in vacuo. Yield 0.36 g, 65%. Recrystallisation from CH₂Cl₂–Et₂O afforded violet needles [Found (Calc. for C₅₅H₅₃ClIMoNO₂P₄): C, 56.5 (56.2); H, 4.6 (4.6); N, 1.3 (1.2)%]. NMR (CD₂Cl₂): ¹H (270.16 MHz) δ 2.65 (2 H, NCH₂) 2.8–3.1 (br m, 8 H, PCH₂CH₂P) superimposed with 3.08 (3 H, s, OCH₃) and 6.5–7.5 (m, 40 H₄ PPh); ³¹P-{¹H} (109.25 MHz), δ –98.0 (s); ¹³C-{¹H} (SiMe₄), δ 27.3 (q, PCH₂), 52.5 (s, OCH₃), 63.3 (s, NCH₂), 128–135 (m, PPh) and 164.4 (s, CO). FTIR (Nujol mull, $\tilde{\nu}$ /cm⁻¹): 1753s [ν(CO)].

trans-[MoCl(NCH₂CO₂Et)(dppe)₂]I.—The complex was prepared as a violet solid in 71% yield using ICH₂CO₂Et by the procedure described above and was converted into the [PF₆] salt by cation exchange with [NH₄][PF₆] in thf and recrystallised from CH₂Cl₂–Et₂O as violet needles [Found (Calc. for C₅₅H₅₅ClF₆MoNO₂P₅-0.5CH₂Cl₂): C, 55.3 (55.8); H, 4.4 (4.6); N, 1.4 (1.1)%]. NMR: ¹H (CDCl₃, 270.16 MHz), δ 0.9 (t, OCH₂CH₃), 2.7 (m, 2 H, NCH₂), 3.4 (q, 2 H, OCH₂); 2.9–3.2 (br m, 8 H, PCH₂CH₂P) and 7.1–7.6 (m, 40 H, PPh); ³¹P-{¹H} (CD₂Cl₂, 109.25 MHz), δ –98.7 (s, MoP) and –285 (qnt, PF₆) FTIR (Nujol mull, $\tilde{\nu}$ /cm⁻¹): 1756s [ν (CO)], 840 and 560s [ν (PF)].

trans-[MoI(NCH₂CO₂Et)(dppe)₂]I.—This complex was prepared in 62% yield from trans-[MoI(N)(dppe)₂] as

described above and converted into the $[PF_6]^-$ salt [Found (Calc. for $C_{56}H_{55}F_6IMoNO_2P_5\cdot0.5CH_2Cl_2$): C, 53.6 (53.1); H, 4.8 (4.4); N, 1.5 (1.1)%]. ¹H NMR (CDCl₃, 270.16 MHz): δ 0.9 (t, 3 H, OCH₂C H_3), 2.7 (m, 2 H, NCH₂), 3.4 (q, 2 H, OCH₂), 2.9–3.2 (br m, 8 H, PCH₂CH₂P) and 7.1–7.6 (m, 40 H, PPh). FTIR (Nujol mull, $\tilde{\nu}/cm^{-1}$): 1745s [ν (CO)], 840 and 560s [ν (PF)].

trans-[MoCl(NCHCO₂Me)(dppe)₂] 2.—The complex trans-[MoCl(NCH₂CO₂Me)(dppe)₂]I (0.2 g, 0.175 mmol) was dissolved in CH₂Cl₂ (20 cm³) and NEt₃ (0.5 cm³) added to the violet solution. The colour changed immediately to greenish yellow. The volume was reduced to about 5 cm³, an equal volume of MeOH was added and the solution was left to stand overnight. Well formed dark green crystals deposited which were filtered off, copiously washed with methanol and dried in vacuo. Yield (0.16 g, 90%) [Found (Calc. for C₅₅H₅₂ClMo-NO₂P₄·0.5CH₂Cl₂): C, 63.1 (63.1); H, 5.2 (5.1); N, 1.3 (1.5)%]. NMR (CD₂Cl₂): 1 H (270.16 MHz); δ 3.28 (qnt, 1 H, NCH), 2.65–2.8 (2 × br m, 8 H, PCH₂CH₂P), 3.00 (3 H, s, OCH₃) and 6.5–7.5 (m, 40 H, PPh); 31 P- 1 H} (109.25 MHz), δ –86.7 (s). FTIR (Nujol mull, $^{\circ}$ /cm⁻¹): 1607, 1622 and 1637s [v(CO), v(C=N)].

trans-[MoCl{NCH(Me)CO₂Me}(dppe)₂]I 3.—The complex trans-[MoCl(NCHCO₂Me)(dppe)₂] (0.165 g, 0.16 mmol) was dissolved in thf (25 cm³) and MeI (0.5 cm³) added. The solution was stirred for 48 h and a pale violet solid precipitated. The solid was filtered off, washed with thf, dried in vacuo and recrystallised from warm MeCN as violet needles. Yield 0.14 g, 74% [Found (Calc. for C₅₆H₅₅ClIMoNO₂P₄): C, 57.9 (58.2); H, 4.9 (4.8); N, 1.2 (1.2)%]. NMR (CD₂Cl₂): ¹H (270.16 MHz), δ 0.27 (d, 3 H, NCHMe), 2.87 (3 H, s, OCH₃), 2.9–3.1 [2 × br m, 9 H, PCH₂CH₂P superimposed with NCHMe (irradiation at δ 3.0 causes collapse of doublet at δ 0.27 to a singlet)] and 6.5–7.5 (m, 40 H, PPh); ³¹P-{¹H} (109.25 MHz), δ –99.4 (s); ¹³C-{¹H}, δ 18.2 (s, NCHMe), 26.8 and 27.5 (m, PCH₂), 52.8 (s, OCH₃), 70.9 (s, NCH), 128–135 (m, PPh) and 167.5 (s, CO). FTIR (Nujol mull, $\tilde{\nu}$ /cm⁻¹): 1748s [ν(CO)].

trans-[MoCl(NCHMe₂)(dppe)₂][BPh₄] 8.—The complex trans-[MoCl(NEt)(dppe)₂][BPh₄] (0.1 g, 0.08 mmol) was partially dissolved in thf (30 cm³) and solid K[OBu¹] (0.026 g, 0.23 mmol) was added to the stirred suspension. A clear orange solution of trans-[MoCl(NCHMe)(dppe)2] rapidly formed to which MeI (0.3 cm³) was then added and the solution stirred overnight at room temperature. The volume of the solution was reduced to 5 cm³ and cooled in ice. The pink solid was filtered off and extracted with the minimum volume of CH₂Cl₂. The filtered extract was taken to dryness and washed with cold thf $(3 \times 5 \text{ cm}^3)$, MeOH $(3 \times 5 \text{ cm}^3)$, Et₂O $(3 \times 5 \text{ cm}^3)$ and dried in vacuo. Yield of pink trans-[MoCl(NCHMe2)(dppe)2][BPh4] 50%. FAB mass spectrum: m/z 986 (M^+) [Found (Calc. for $C_{79}H_{75}BCIMoNP_4$): C, 72.9 (72.7); H, 6.5 (5.8); N, 1.1 (1.1)%]. NMR (CD₂Cl₂): ¹H (270.16 MHz); $\delta - 0.12$ (d, 6 H, CH₃, J =6.7), 2.48 [m, 1 H, NCHMe₂, J = 6.7 Hz], 2.6–2.9 (two br m, 8 H, PCH₂CH₂P) and 6.8–7.5 (m, 60 H, PPh and BPh); ³¹P-{¹H} (109.25 MHz), δ -98.1 (s).

trans-[MoCl(NBu)(dppe)₂][BPh₄] 7.—This compound was prepared in 70% yield by the reaction of deprotonated trans-[MoCl(NMe)(dppe)₂][BPh₄] with n-propyl iodide following an analogous procedure to that described above. The pink product was recrystallised from CH_2Cl_2 – Et_2O . FAB mass spectrum: m/z 1000 (M^+) [Found (Calc. for $C_{80}H_{77}BClMo-NP_4·0.5CH_2Cl_2$): C, 70.6 (71.0); H, 6.3 (5.8); N, 1.1 (1.0)%].

Complex 6 was made in ca. 70% yield from trans-[MoCl(NMe)(dppe)₂][BPh₄] and MeI following the same procedure; spectroscopic data identical to the sample prepared by ethylation of the nitride as described above.

trans-[MoCl(NCH=CHMe)(dppe)₂][BPh₄] K[OBu¹] (0.04 g, 0.34 mmol) was added to a stirred suspension of trans-[MoCl(NCH₂CH=CH₂)(dppe)₂]I (0.12 g, 0.11 mmol) in thf (30 cm^3) and a deep orange solution of the intermediate trans-[MoCl(N=CHCH=CH₂)(dppe)₂] was rapidly formed. At room temperature, HBF₄·OEt₂ (ca. 50% in Et₂O, 0.1 cm³) was added to the stirred solution, which changed from orange to pale red. The reaction mixture was stirred for 1 h and the solution filtered through Celite to remove KI. The filtrate was evaporated to dryness and extracted with the minimum volume of CH₂Cl₂, filtered, evaporated to dryness and taken up in the minimum volume of methanol. Addition of NaBPh₄ (ca. 0.2 g) to the methanolic solution precipitated the product as the [BPh₄] salt which was filtered off and recrystallised from CH₂Cl₂-Et₂O as a metallic silver-rose microcrystalline solid in 55% yield. FAB Mass spectrum. m/z 984 (M^{+}) [Found (Calc. for $C_{79}H_{73}BClMoNP_4$ -0.25CH₂Cl₂): C, 71.8 (71.9); H, 5.8 (5.6); N, 1.1 (1.1%)]. NMR (CD₂Cl₂): ¹H (270.16 MHz) δ 0.94 [d, 3 H, CHCH₃, J_{H-Me} = 7], 2.6–2.9 (2 × m, 8 H, PCH₂-CH₂P) 4.13 [sxt, 1 H, NCH=CHMe, J_{trans} = 15, J_{H-Me} = 7] 4.44 [dm, 1 H, NCH=CHMe, J_{trans} = 15 Hz] and 6.8–7.5 (m, 60 H, PPh and BPh); ³¹P-{¹H} (109.25 MHz), δ – 97.2 (s).

trans-[MoCl(NCH=CHEt)(dppe)₂][BPh₄] 12.—This complex was prepared in an analogous fashion to the methyvinylimide by addition of MeI (ca. 0.3 cm³) to the deprotonated allylimide and stirring the reaction mixture overnight. Work-up as before and recrystallisation from thf-Et₂O gave the silver-rose microcrystalline product in 50% yield. FAB mass spectrum: m/z 998 (M^+) [Found (Calc. for C₈₀H₇₅BClMoNP₄): C, 73.9 (73.0); H, 6.0 (5.8); N, 1.2 (1.1%)]. ¹H NMR (CD₂Cl₂): ¹H (270.16 MHz), δ 0.53 (t, 3 H, CH₂CH₃, J = 7.4), 1.32 (qnt, 2 H, CH₂CH₃, J = 6.5 and 7.4 Hz) 2.6–2.9 (2 × br m, 8 H, PCH₂CH₂P), 4.26 (qnt, 1 H, CH=CHCH₂), 4.40 (dm, 1 H, NCH=CH), and 6.8–7.5 (m, 60 H, PPh and BPh); ³¹P-{¹H} (109.25 MHz), δ –97.7 (s).

Formation of Cyanoformic acid Ethyl Ester, NCCO₂Et.—The complex trans-[MoI(NCH₂CO₂Et)(dppe)₂]I (0.17 g, 0.14 mmol) was suspended in thf (40 cm³) and solid K[OBu^t] (0.07 g, 0.57 mmol) was added to the stirred solution which rapidly changed from pale violet to green. Dinitrogen was passed through the stirred solution for 44 h during which time it changed to orange-red. Concentration of the solution to a small volume gave orange microcrystalline trans- $[Mo(N_2)_2(dppe)_2]$ which was filtered off, washed with MeOH and dried in vacuo. Yield = 0.076 g, 0.08 mmol (57%); $v(N_2)$ 1980 cm⁻¹ (Nujol mull); $E_{\downarrow}^{\text{ox}} = 0.70 \text{ V}$ versus ferrocenium-ferrocene. Addition of Et₂O to the filtrate precipitated a small amount of unidentified green material which was filtered off. The filtrate was transferred to a volumetric flask, diluted to volume with thf and analysed by HPLC using a Merck-LIChroCart 250-4 RP 18, 5 µm column. The sole organic product was identified as NCCO₂Et formed in 55% yield. Its identity was confirmed by evaporation of the filtrate and liquid-film IR spectroscopy. Strong bands observed at v(CN) 2250 cm⁻¹ and v(CO) 1743 cm⁻¹ are identical to those of an authentic sample.

The procedure was repeated except that carbon monoxide rather than dinitrogen was passed through the solution. The complex [Mo(CO)₂(dppe)₂] (cis and trans isomers) was formed and isolated as a yellow solid in 80% yield. Also HPLC showed that NCCO₂Et was formed in 80% yield; the green by-product was not obtained under these conditions. Repeating the same experiment under CO but employing trans-[MoCl(NCH₂CO₂-Et)(dppe)₂]I rather than the iodo-complex, gave the same products but in somewhat lower yields (70% complex, 70% ester).

trans-[Mo(N₂)(NCCO₂Et)(dppe)₂].—This complex was prepared by modifying the general method of Hidai and coworkers ¹⁰ for related nitrile complexes. The complex trans-

[Mo(N₂)₂(dppe)₂] (0.23 g, 0.24 mmol) was dissolved in thf (40 cm³) and ethyl cyanoformate (0.1 cm³, 1.0 mmol) added to the stirred solution. The reaction mixture was irradiated for 4.5 h with a tungsten-filament lamp (300 W) during which time it changed from orange to red. Concentration of the solution under vacuum afforded a red precipitate which was filtered off, washed with Et₂O and dried *in vacuo*. Recrystallisation from thf–Et₂O gave the product as a red microcrystalline solid (0.13 g, 0.13 mmol) in 53% yield [Found (Calc. for C₅₂H₄₅MoN₃P₄): C, 65.8 (65.8); H, 5.5 (5.2); N, 4.1 (4.1)%]. ¹H NMR (CD₂Cl₂, 270.16 MHz): δ 1.05 (t, 3 H, CH₂CH₃) 3.30 (q, 2 H, OCH₂CH₃) 2.7–3.1 (2 × br m, 8 H, PCH₂CH₂P) and 6.8–7.5 (m, 40 H, PPh). FTIR (Nujol mull, $\tilde{\nu}$ /cm⁻¹): 1710s [ν (CO)]; 2094s [ν (N₂)] and 2170w [ν (CN)].

trans-[Mo(N₂)(NCCO₂Et)(dppe)₂] (0.09 g, 0.08 mmol) was stirred under dinitrogen in thf for 15 h. Removal of the solvent under vacuum and examination of the residue by FTIR spectroscopy (Nujol mull, \tilde{v}/cm^{-1}) showed the formation of the free ester, 1744s, [v(CO)] and 2247w [v(CN)], trans-[Mo(N₂)₂(dppe)₂] (1997) together with the unreacted starting material. The formation of trans-[Mo(N₂)₂(dppe)₂] was also confirmed by cyclic voltammetric experiments in thf–0.2 mol dm⁻³ [NBu₄][BF₄] at Pt: the reversible oxidation process for trans-[Mo(N₂)(NCCO₂Et)(dppe)₂] at $E_{\frac{1}{2}} = -0.44$ V versus ferrocenium–ferrocene was gradually replaced by that for trans-[Mo(N₂)₂(dppe)₂] ($E_{\frac{1}{2}} = -0.70$ V) on purging the solution with dinitrogen.

Formation of Glycine and DL-Alanine Methyl Esters.—The complex trans-[MoCl(NCH₂CO₂Me)(dppe)₂]I (0.08 g, 0.07 mmol) was dissolved in thf–0.2 mol dm⁻³ [NBu₄][BF₄] (ca. 15 cm³) which was contained in the working-electrode compartment of the H-type electrochemical cell. Glacial acetic acid (1.5 cm³) was added to the solution of the complex. Electrolysis was carried out under argon at a vitreous carbon cathode of nominal area 2 cm² at an applied potential of -2.3 V versus ferrocenium–ferrocene. The catholyte was stirred at an even

rate during electrolysis using a magnetic follower and the current was monitored continuously as a function of the charge passed. The solution changed during electrolysis from pink through red to a deep orange and the current decayed to a steady-state value. The electrolysis was terminated after the passage of 5F mol⁻¹ of charge and the orange solution removed from the cell by a gas-tight syringe. On standing for *ca*. 0.5 h the solution changed to bright magenta as [MoH- $(\eta^2-O_2CMe)(dppe)_2$] was slowly converted into [MoH₂ $(\eta^2-O_2CMe)(dppe)_2$]⁺. The formation of the glycine ester was confirmed by TLC and quantified colorimetrically with ninhydrin, ¹³ yield based on complex = 70%, current yield = 56%. Alanine methyl ester was electrosynthesised by the same procedure, yield based on complex = 80%, current yield = 64%.

Crystal Structure Analyses.—The analyses of three crystals are reported, of compound 2 and of two forms of compound 3 (a and b). The procedures followed for 2 are described; those for 3 were very similar. Crystal data and details of the analyses are in Table 6.

Crystals of complex 2 range from red to very dark red; some were dichroic red-green. One was mounted on a glass fibre and, after photographic examination, transferred to an Enraf-Nonius CAD4 diffractometer [with monochromated radiation, $\lambda(\text{Mo-K}_{\alpha}) = 0.710$ 69 Å] for determination of accurate cell dimensions (from the settings of 25 reflections, θ ca. 10.5° , each reflection centred in four orientations) and for measurement of diffraction intensities. During processing, the intensities were corrected for Lorentz-polarisation effects and adjusted by Bayesian statistical methods to ensure no negative net values. No corrections for crystal deterioration or absorption were applied [N.B. crystals 3a and 3b both showed slight deterioration; corrections for absorption (by semiempirical ψ -scan methods) were applied to 3b].

The structure of complex 2 was determined by the heavyatom method in the SHELX system; 14 3b was solved similarly,

but 3a required use of the automated Patterson routines in SHELXS. 15 Refinement was by large-block-matrix leastsquares methods with all principal atoms allowed anisotropic thermal parameters. Hydrogen atoms in the diphosphine ligands were included in idealised positions. Refinement of the inverted structure showed no significant differences. There is disorder of the ClMo(amide) group and of the CH₂Cl₂ solvent molecule which lies close to the chloride ligand; this grouping lies in opposing directions, in the ratio of ca. 4:1, in the major and minor components in the crystal. The atoms in the minor component [except for Mo' and Cl(5')] were refined isotropically. In the final difference map there was a peak where we would have expected to find H(61), in the plane of the amide ligand; the atom was not included in the structure-factor calculation but is shown in Fig. 1(a).

There is disorder also in the crystals of both 3a and 3b. In 3a one of the two acetonitrile molecules is disordered over several orientations and the 'solvent' molecule (believed to be thf) is poorly resolved; the cation appears well resolved and it is this structure that has been described elsewhere. The hydrogen atoms in the imide ligand were included in calculated positions; those of the methyl groups were allowed to refine with geometrical constraints. Crystal 3b shows disorder in the acetonitrile molecule and in the imide ligand; either enantiomer can be accommodated equally, such that the N(6), C(62), O(63)and C(64) atom sites are common (or very nearly so) to both enantiomers, with the other atoms either side of a pseudomirror plane.

Scattering factor curves for neutral atoms were taken from ref. 16. Computer programs used in the analyses have been noted above and in Table 4 of ref. 17, and were run on a DEC MicroVAX 3600 machine in the Nitrogen Fixation

Additional material available from the Cambridge Crystallographic Data Centre comprises H-atom coordinates, thermal parameters and remaining bond lengths and angles.

Acknowledgements

We gratefully thank Dr. Ali Abdulsadda of the School of Chemistry and Molecular Science, University of Sussex, for FAB mass spectral measurements. The Calouste Gulbenkian Foundation and the Universidade do Minho are thanked for providing travel funds for A. F.
