A series of new 2'–5' oligonucleotides carrying the 9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenine moiety as a building block has been synthesized *via* the phosphotriester method. The use of the 2-(4-nitrophenyl)ethyl (npe) and 2-(4-nitrophenyl)ethoxycarbonyl (npeoc) blocking groups for phosphate, amino, and hydroxy protection guaranteed straightforward syntheses in high yields and easy deblocking to form the 2'–5' trimers **21**, **22**, and **25** and the tetramer **23**. Catalytic reduction of the azido groups in [9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenin]-2'-yl-[2'-(*O*^p-ammonio)→5']-[9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenin]-2'-yl-[2'-(*O*^p-ammonio)→5']-9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenine (**21**) led to the corresponding 9-(3'-amino-3'-deoxy- β -D-xylofuranosyl)adenine 2'–5' trimer **26** in which the two internucleotidic linkages are formally neutralized by intramolecular betaine formation.

1. Introduction. – Ever since the isolation and characterization of 5'-*O*-triphosphoryl-adenylyl(2'–5')adenylyl(2'–5')adenosine [2] as a very potent low-molecular-weight inhibitor of cell-free protein synthesis was achieved, oligomeric (2'–5')adenylates and structural analogues [3] have attracted much attention. Since the natural oligomeric (2'–5') adenylates lose rapidly their biological activity due to cleavage of the internucleotidic bond by a specific phosphodiesterase, much efforts have been directed towards the synthesis of base-, sugar-, and phosphate-modified analogues to improve enzymatic stability and to increase the poor uptake of the polar molecules into intact cells [3]. A supplementary problem to preserve the antiviral and antineoplastic activity is the design of such 2'–5'A analogues which not only will be potentially resistant to enzymic degradation but still have the ability to bind and activate the 2'–5'A dependent endonuclease [4–8]. We present here the synthesis of different oligonucleotides containing 9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenine (**1**) as the modified adenosine analogue. Reduction of the azido functions will, furthermore, allow the development of a formally neutral molecule at physiological pH by inner-salt formation of the betaine type.

2. Syntheses. – The chemical syntheses of the new 2'–5' oligonucleotides were achieved in a stepwise approach from the appropriately protected monomeric building blocks *via* the phosphotriester method [9–11]. Starting from 9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenine (**1**) [12], transient trimethylsilyl protection at the sugar moiety [13] was first performed and then the NH₂ group blocked by the 2-(4-nitrophenyl)ethoxycarbonyl (npeoc) residue [14] to give **2** in almost quantitative yield. Monomethoxytritylation to **3** proceeded also very well, and subsequent acylation of the 2'-OH group using 1-methyl-3-[2-(4-nitrophenyl)ethoxycarbonyl]imidazolium chloride [14] gave **4** in 93% yield. Detritylation of **4** to *N*⁶-[2-(4-nitrophenyl)ethoxycarbonyl]-9-{2'-*O*-[2-(4-nitrophenyl)ethoxycarbonyl]-3'-azido-3'-deoxy- β -D-xylofuranosyl}adenine (**5**) worked best (90% yield) with *p*-toluenesulfonic acid in CH₂Cl₂/MeOH. In the next step, **3** was converted into the mixed phosphotriester **6** by phosphorylation using a mixture of 2,5-dichlorophenyl dichlorophosphate and 1,2,4-triazole and followed by 2-(4-nitrophenyl)ethanol treatment. Phosphotriester **6** was then transformed by detritylation into **7** in 96% yield and, by oximate treatment, into the corresponding phosphodiester **8** in 93% yield. The 5'-phosphotriester **9** resulted from **5** on treatment with bis[2-(4-nitrophenyl)ethyl] chlorophosphate [15], and the building block **10** was obtained from *N*⁶-[2-(4-nitrophenyl)ethoxy-carbonyl]adenosine [14] by *Markiewicz's* protecting procedure [16].

The dinucleoside phosphotriester **11** was formed in excellent yield from **5** and **8** using 2,4,6-triisopropylbenzenesulfonyl chloride and *N*-methylimidazole as condensing agents. Detritylation gave a 95% yield of **12**, the good yield being mainly due to the stable amino protection by the npeoc group. Another dimer synthesis was successfully achieved with the components **7** and **8** yielding 88% of **13** under the usual reaction conditions. Selective cleavage of the 2'-terminal 2,5-dichlorophenyl phosphate protecting group by the oximate method led to the anticipated dimeric phosphodiester **14**. The introduction of a mixed phosphotriester function into **12** giving **15** proceeded also very well according to standard procedures. The 5'-terminal dimeric phosphodiester **16** was obtained from **15** by oximate treatment. The purification of this triethylammonium salt **16** caused difficulties so that no accurate elemental analysis was obtained as it is often the case with this type of compounds.

The buildup of the various trimers and the tetramer was achieved by the same phosphotriester methodology and led again to excellent yields in the condensation steps. The trinucleoside (2'–5')-diphosphoditriester **17** was obtained from two different routes condensing either **8** and **12** or **5** and **14**. Detritylation of **17** afforded **18** in 93% yield, and the phosphorylation led to the trinucleoside triphosphotriester **19**. The tetramer **20** resulted from a block condensation using the 5'-OH free dimer **12** and the dimeric 2'-terminal phosphodiester **14**.

The deprotection of **18**–**20** to the free oligonucleotides **21**–**23**, respectively, turned out to be a straightforward process due to the uniform type of blocking groups. Thus, the npe and npeoc groups of **18** and **19** were cleaved in only one step by DBU (1,8-diazabicyclo[5.4.0]undec-7-ene) with β -elimination, and in the case of **20**, only one additional acid treatment was necessary to free the tetramer. Isolation and purification were performed by *DEAE-Sephadex* and paper chromatography to give the ammonium salts **21**–**23** as lyophilized powders.

Furthermore, the phosphodiester **16** was condensed with *N*⁶-[2-(4-nitrophenyl)ethoxycarbonyl]-3',5'-*O*-(1,1,3,3-tetraisopropylidisiloxan-1,3-diyl)adenosine (**10**) in the

MeOTr = monomethoxytrityl; npe = 2-(4-nitrophenyl)ethyl;

usual manner applying 2,4,6-triisopropylbenzenesulfonyl chloride and either *N*-methylimidazole or 4-(dimethylamino)pyridine *N*-oxide, but the 30% isolated yield of **24** was unexpectedly low. Deblocking in two steps using DBU/pyridine followed by Et₃NHF in THF gave, after purification, a 58% yield of **25**.

In a final experiment, the 2'-5' trimer **21** was catalytically reduced with Pd/C and H₂ at normal pressure to the corresponding 3'-amino-3'-deoxy-xylo-nucleotide trimer **26**.

Studies on the chemical and enzymatic stability of the free oligonucleotides **21–23** and **26** revealed complete resistance towards 0.33N NaOH for 24 h at 37° due to the absence of any 3'-neighbouring group that could catalyse the internucleotidic hydrolysis, but with snake-venom phosphodiesterase, a complete digestion from the 2'-end took place.

1. 9-(3'-Azido-3'-deoxy- β -D-xylofuranosyl)-N⁶-[2-(4-nitrophenyl)ethoxycarbonyl]adenine (**2**). A suspension of 2.92 g (10 mmol) of 9-(3'-azido-3'-deoxy- β -D-xylofuranosyl)adenine [12] (**1**) in dioxane (3 ml), hexamethyldisilazane (3 ml), and a catalytic amount of (NH₄)₂SO₄ were refluxed for 3 h. The mixture was cooled to r.t., evaporated, and treated with 12 ml of abs. toluene. The suspension was filtered and the filtrate evaporated. To the oily residue in anh. CH₂Cl₂ (40 ml), 6.23 g (20 mmol) of 1-methyl-3-[2-(4-nitrophenyl)ethoxycarbonyl]imidazolium chloride were added. The suspension was stirred for 36 h at r.t., the mixture filtered and evaporated, and the residue dissolved in MeOH (100 ml). After addition of 16% aq. NH₃ soln. (15 ml), the mixture was kept at r.t. for 45 min and then evaporated. The residue was chromatographed on silica gel with CHCl₃/MeOH 98:2 and 95:5. The main fraction gave, on recrystallization from i-PrOH, 4.76 g (96%). M.p. 102° (soften). b) A mixture of 1.52 g (2 mmol) of **3**, 72 mg (0.6 mmol) of 4-(dimethylamino)pyridine, and 1.25 g (4 mmol) of 1-methyl-3-[2-(4-nitrophenyl)ethoxycarbonyl]imidazolium chloride in CH₂Cl₂ (20 ml) was stirred at r.t. for 20 h. CH₂Cl₂ (20 ml) was added and the mixture washed 3 times with H₂O (40 ml), dried, and evaporated. The resulting light-yellow foam was dissolved in CH₂Cl₂/MeOH 4:1 (40 ml) containing 800 mg of TsOH·H₂O and kept at r.t. for 30 min. The mixture was diluted with CHCl₃ (60 ml), washed 3 times with phosphate buffer pH 7.0 (0.15M; 3 × 100 ml), dried, and evaporated. The resulting foam was purified by silica-gel column chromatography with AcOEt: 1.8 g (88%) of amorphous solid.

5. 9-[3'-Azido-3'-deoxy-5'-O-(monomethoxytrityl)-β-D-xylofuranosyl]-N⁶-[2-(4-nitrophenyl)ethoxycarbonyl]adenin 2'-[2,5-Dichlorophenyl 2-(4-Nitrophenyl)ethyl Phosphate] (**6**). A mixture of 1.68 g (6 mmol) of 2,5-dichlorophenyl dichlorophosphate and 0.90 g (13 mmol) of 1,2,4-triazole were stirred for 20 min at r.t. in abs. pyridine (16 ml). The suspension was cooled in an ice-bath and a soln. of 3.03 g (4 mmol) of **3** in abs. pyridine (24 ml) added dropwise. The mixture was stirred for 30 min and then warmed to r.t. After addition of 1.34 g (8 mmol) of 2-(4-nitrophenyl)ethanol, the mixture was stirred over night at r.t., evaporated, diluted with H₂O (100 ml), and extracted with CHCl₃ (2 × 100 ml). The org. layer was washed with H₂O (100 ml), dried, evaporated, and coevaporated with toluene. The mixture was stirred at r.t. for 40 h, evaporated, diluted with CHCl_3 (10 ml), washed twice with H_2O (2×10 ml), dried, evaporated, and coevaporated with toluene. The mixture was purified by silica-gel column chromatography (CHCl_3 then $\text{CHCl}_3/\text{MeOH}$ 96:4). Since the main fraction contained *N*-methylimidazole ($^1\text{H-NMR}$), further purification was necessary. The product was dissolved in CHCl_3 (5 ml), washed twice with H_2O (2×5 ml), dried, evaporated, and chromatographed on a silica-gel column with $\text{CHCl}_3/\text{MeOH}$ 97:3 to give 96 mg (31%) of an amorphous solid.

b) To a soln. of 230 mg (0.135 mmol) of **16**, 141 mg (0.2 mmol) of **10**, and 124 mg (0.9 mmol) of 4-(dimethylamino)pyridine *N*-oxide in pyridine (2 ml) were added 91 mg (0.3 mmol) of 2,4,6-triisopropylbenzenesulfonyl chloride. The mixture was stirred for 40 h at r.t., evaporated, dissolved in CHCl_3 (10 ml), washed 3 times with H_2O (10 ml), dried, evaporated, and coevaporated with toluene. Purification was achieved by silica-gel column chromatography (CHCl_3 , then $\text{CHCl}_3/\text{MeOH}$ 97:3). The main fraction was further purified by prep.
