1,2,5,6,9,10-Hexaalkoxyhexahelicenes **3** represent [3]star compounds with a helical core. A multi-step synthetic concept for **3** is discussed, in which the final step **16** → **3** is a twofold oxidative photocyclization. The linearly conjugated compounds **16** contain stilbene and vinylnaphthalene units.

Key words: Helicenes, Photocyclization, Wittig–Horner Reaction, Siegrist Reaction

Introduction

[3]Star compounds, which consist of conjugated aromatic cores and three, six or nine alkoxy groups, represent interesting structures for materials science [1]. 2,3,6,7,10,11-Hexaalkoxytriphenylenes (**1**) are prominent examples (Fig. 1). From their first preparations [2, 3] till our days [4–9], a large variety of compounds **1** have been thoroughly studied. Much less is known about 1,2,5,6,9,10-hexaalkoxycoronenes (**2**) [10, 11], and nothing is known about 1,2,5,6,9,10-hexaalkoxyhexahelicenes (**3**). In contrast to **1** and **2**, compound **3** has a non-planar, chiral polycyclic core. Many mesophases are known for compounds **1**, some for systems **2**. This arises the question: Do chiral thermotropic liquid crystalline phases (LC) exist for **3**? Due to the lack of symmetry, the usual synthesis of hexahelicenes on the basis of 2,7-distyrylnaphthalenes [12], is not useful

in this case. We conceived a multi-step procedure, which starts from benzene and naphthalene derivatives.

Results and Discussion

Scheme 1 summarizes the preparation of the 2-[4-(2-phenylvinyl)phenyl]vinyl]naphthalenes **16a, b**, which were chosen as precursors for the desired hexahelicenes **3**.

3-Methylbenzene-1,2-diol (**4**) was alkylated twice under phase transfer conditions [13, 14]. We used long alkyl chains to get high solubilities throughout the whole reaction sequence. The obtained 3-methyl-1,2-dialkoxybenzenes **6a, b** were subjected to a Bouveault formylation to **7a, b**. The formylation was neither regioselective nor chemoselective; the CH₃ group was also attacked by DMF [15, 16]. Consequently the yields of **7a, b** were low. In a second reaction se-

quence, **6a, b** were transformed to the phosphonates **9a, b** via the bromides **8a, b** [14]. Wittig–Horner reactions **7a+9a** and **7b+9b** gave the (*E*)-configured stilbenes **10a** and **10b**, respectively.

The naphthalene moiety of **16a, b** was synthesized on the basis of the ester **11** [17, 18], which was alkylated with the bromoalkanes **5a, b** to obtain **12a, b**. Reduction with LiAlH₄ yielded the alcohols **13a, b**.

b, which were gently oxidized by 2,3-dicyano-5,6-dichloro-1,4-benzoquinone (DDQ) to the aldehydes **14a, b**. The reaction with aniline gave then the Schiff bases **15a, b**. In contrast to the left branch of the synthetic Scheme 1, all yields in the right branch are very high. The four steps from **11** to **15a** have for example an overall yield of $88 \times 0.94 \times 0.95 \times 100 = 78.6\%$. Siegrist reactions [19] of **10a+15a** and **10b+15b** gave then **16a** and **16b**, respectively. The stereoselectivity

in favor of the *(E)*-configuration is so high that the *(Z)*-isomers could not be detected in the NMR spectra of the crude reaction products **16a, b** [20].

Irradiation of *(E,E)*-**16a, b** led to the formation of the two possible *(E,Z)*-isomers and the *(Z,Z)*-isomer, which subsequently underwent cyclization and oxidation to **17a, b** and/or **18a, b** (Scheme 2). The second photocyclization and oxidation gave **3a** and **3b**, respectively, in good overall yields. In principle, an

unsubstituted system **16** would have four cyclization modes, which can lead to four different condensed benzenoid aromatics; however, the alkoxy groups in **16a**, **b** block three cyclization routes, so that only the route **16a**, **b** \rightarrow **3a**, **b** remains. Iodine served as oxidant and methyloxirane as scavenger for the generated hydrogen iodide [21]. At the stage of the not isolated intermediates **17** and/or **18**, photoisomerizations have to be assumed.

The racemates **3a** and **3b** are pale-yellow oils which solidify below -20°C . Both compounds exhibit very different DSC curves (Fig. 2); however, the formation of thermotropic mesophases could be excluded by polarization microscopy. Liquid crystals are very rare in the series of hexahelicenes [22, 23]. The broad peak in the heating and cooling curve of **3a** is unusual. It can be possibly due to a superposition of several closely lying phase transitions in the solid state. Impurities and

The hexahelicenes **3a**, **b** belong to the point group C_1 , they are chiral. Consequently they show ten aromatic CH signals, ten C_q and six $C_q\text{O}$ signals in the ^{13}C NMR spectra. Most characteristic are their ^1H NMR signals (Table 1). The aromatic protons give three AB and one ABCD spin patterns. The signals at highest field in the aromatic region were found for 11-H at $\delta = 6.33$ and 6.32 ppm, respectively. The overlap of the terminal benzene rings and the high electron density, induced by the 10-OR groups, are the reason for the resonance at unusually high field.

Conclusion

The hexahelicenes **3a** and **3b** are the first examples of [3]star compounds with a helical core consisting of a hexahelicene structure. Their preparation in a multistep synthesis was based on the twofold oxidative photocyclization of the linearly conjugated 2-(4-styryl-styryl)naphthalenes **16a** and **16b** (Schemes 1 and 2).

Experimental Section

NMR spectra were recorded on a Bruker AM 400 spectrometer operating at 400 MHz for ^1H and 100 MHz for ^{13}C .

FD MS (5 kV) and EI MS (70 eV) measurements were performed with a Finnigan MAT 95 spectrometer. UV/Vis spectra were obtained with a Zeiss MCS 320/340 diode array spectrometer. Melting points were taken on a Büchi apparatus and are uncorrected. A Perkin-Elmer DSC 7 instrument served for the differential scanning calorimetry (DSC). Polarization microscopy was performed with a Leitz Ortholux II microscope. Elemental analyses were determined in the microanalytical laboratory of the Chemistry Department of the University of Mainz.

The synthetic sequence **4** → **6a**, **b** → **8a**, **b** → **9a**, **b** is described elsewhere [14].

It was not necessary to isolate the intermediate bromo compounds **8a**, **b**. However, the oily compound 2,3-bis(hexyloxy)benzylbromide (**8a**) was checked for its purity by NMR control. – ^1H NMR (CDCl_3): δ = 0.88–1.01 (m, 6 H, CH_3), 1.25–1.45 (m, 8 H, CH_2), 1.45–1.61 (m, 4 H, CH_2), 1.75–1.94 (m, 4 H, CH_2), 3.95 (t, 3J = 6.3 Hz, 2 H, OCH_2), 4.13 (t, 3J = 6.6 Hz, 2 H, OCH_2), 6.83 (dd, 3J = 6.8 Hz, 4J = 2.9 Hz, 1 H, 4-H), 6.89–7.02 (m, 2 H, 5-H, 6-H). – ^{13}C NMR (CDCl_3): δ = 13.9, 14.0 (CH_3), 22.5, 22.6, 25.7, 25.8, 29.7, 30.3, 31.5, 31.7 (CH_2), 28.3 (CH_2Br), 113.7 (C-4), 122.3, 123.7 (C-5, C-6), 131.9 (C-1), 146.7, 152.3 (C-2, C-3). The only visible impurity was the starting compound **6a**, which does not react with triethyl phosphite.

Bouveault formylation of **6a**, **b** to **7a**, **b**

Benzene derivative **6a**, **b** (22.0 mmol) and *N,N'*-tetramethylethylenediamine (TMEDA, 3.0 mL, 33.0 mmol) were dissolved in 100 mL of dry and deoxygenated diethyl ether. A 2.7 M solution of *n*-butyllithium in hexane (21.0 mL, 33.0 mmol) was added and the mixture stirred for 3 h at ambient temperature, before dimethylformamide (DMF, 2.3 mL, 33.0 mmol) was added. After a further hour at room temperature, first H_2O (10 mL) and then 2 M HCl (10 mL) were slowly dropped into the mixture. The organic layer and the extract of the water layer (50 mL diethyl ether) were unified, neutralized (NaHCO_3), dried (MgSO_4) and evaporated. The residue was purified by column filtration (5×40 cm SiO_2 , toluene or CH_2Cl_2).

Wittig–Horner reaction of **7a**, **b** and **9a**, **b** for the preparation of **10a**, **b**

Phosphonic acid ester **9a**, **b** (2.1 mmol) in 40 mL of dry dimethoxyethane (DME) was dropped under nitrogen to NaH (420 mg, 10.5 mmol, 60% in paraffin) suspended in 120 mL of dry DME. Aldehyde **7a**, **b** (2.1 mmol) was slowly added and the reaction mixture heated to reflux for 6 h. Then 40 g crushed ice was added and the aqueous phase extracted with 100 mL of diethyl ether. The unified organic phases were dried (MgSO_4) and evaporated. The residue was purified by column chromatography (3×40 cm SiO_2 , petroleum ether, b. p. 40–70 °C / CH_2Cl_2 2 : 1).

Formation of the Schiff bases 15a, b

Aldehyde **14a, b** (3.40 mmol) and aniline (400 mg, 4.30 mmol) were dissolved in 60 mL of CHCl_3 and heated to reflux for 1 d, so that the formed H_2O was continuously removed. The volatile parts were distilled off and the residue dried at 0.1 kPa. The obtained oily products were analytically pure.

[1-[3,4-Bis(hexyloxy)naphthalen-2-yl]methylidene]-phenylamine (15a)

Quantitative yield: 1.46 g, pale-yellow oil. – ^1H NMR (CDCl_3): δ = 0.82–0.98 (m, 6 H, CH_3), 1.20–1.42 (m, 8 H, CH_2), 1.42–1.65 (m, 4 H, CH_2), 1.65–1.96 (m, 4 H, CH_2), 4.13–4.23 (m, 4 H, OCH_2), 7.23–7.57 (m, 7 H, aromat. Siegrist reaction of the Schiff bases 15a, b and the methylstilbenes 10a, b

Methylstilbene **10a, b** (3.0 mmol) and Schiff base **15a, b** (3.3 mmol) were treated in 150 mL of dry DMF with 3.8 g (34.0 mmol) $\text{KOC}(\text{CH}_3)_3$ at room temperature. After 0.5 h the reaction mixture was heated to 90 °C and stirred for 1.5 h. Then 30 mL of H_2O and 50 mL of 2 M HCl were slowly added. The mixture was extracted with 3×120 mL of diethyl ether. The neutralized (NaHCO_3) ether solution was dried (MgSO_4) and evaporated. The residue was purified by column filtration (4×40 cm SiO_2 , toluene).

1,2-Bis(hexyloxy)-3-((E)-2-{2,3-bis(hexyloxy)-4-[(E)-2-(2,3-bis(hexyloxy)phenyl)vinyl]phenyl}vinyl)naphthalene (16a)

Stilbene **10a** (1.8 g, 3.0 mmol) and Schiff base **15a** (1.4 g, 3.3 mmol) yielded 1.71 g (61 %) **16a** as yellow oil. – ^1H NMR (CDCl_3): δ = 0.83–0.96 (m, 18 H, CH_3), 1.20–1.40 (m, 24 H, CH_2), 1.44–1.59 (m, 12 H, CH_2), 1.75–1.90 (m, 12 H, CH_2), 3.95–4.16 (m, 12 H, OCH_2), 6.80 (d, 3J = 8.1 Hz, 1 H, aromat. Preparation of the phenanthro[3,4-*c*]phenanthrenes **3a**, **b**

A solution of 0.7 mmol **16a**, **b** and 0.35 g (1.4 mmol) I₂ in 2 L of dry benzene was purged by a stream of oxygen-free nitrogen for 0.5 h. Methyloxirane (4.9 mL, 70 mmol) was added and the mixture irradiated with a Hanovia-450 W medium-pressure lamp equipped with a Pyrex filter. The red solution bleaches in the course of the reaction which takes

10–12 h. The N₂ stream was maintained till the process came to an end. The reaction mixture was treated with aqueous NaHCO₃, dried (MgSO₄) and evaporated. The crude product was purified by a twofold column chromatography (3 × 50 cm SiO₂, petroleum ether, b.p. 40–70 °C / CH₂Cl₂ 5 : 1 to 2 : 1).
