

## Convenient Synthesis of Allenyl Sulphides; Application to the Synthesis of $\alpha\beta$ -Unsaturated Ketones<sup>†</sup>

By RICHARD C. COOKSON\* and PHILIP J. PARSONS

(Chemistry Department, University of Southampton, Southampton SO9 5NH)

**Summary**  $P_2S_5$  in methylene chloride containing pyridine reduces allenyl phenyl sulfoxides to sulphides; the difficult hydrolysis of the latter is eased by the introduc-

tion of a methoxy group into the benzene ring and this method then becomes a practicable synthesis of  $\alpha\beta$ -unsaturated ketones.

No reprints available.

ALLENYL 'SULPHOXIDES (2)' are easily made from propynyl alcohols and benzenesulphenyl chloride.<sup>1</sup> We find that the sulphoxides (2) are readily metallated with *n*-butyl-lithium

SCHEME 1. i, PhSCL or *p*-MeOC<sub>6</sub>H<sub>4</sub>SCL, Et<sub>3</sub>N, Et<sub>2</sub>O, -20 to -30 °C; ii, Bu<sup>n</sup>Li, Et<sub>2</sub>O, -78 °C; iii, electrophile, *e.g.*, MeI, RCHO, R<sub>2</sub>CO.

in ether, and are then alkylated with a variety of electrophiles (Scheme 1). However, reaction of the lithium derivative (3) with epoxides is sluggish, and to make the

organolithium reagents more nucleophilic, the oxygen atom was removed. Lithium aluminium hydride in ether reduced the allenyl sulphoxides (2) and (4) to the allyl sulphides (6) and (5) in almost quantitative yield (hence an equivalent of exclusively  $\alpha$ -alkylation in allyl systems). P<sub>2</sub>S<sub>5</sub> in dry methylene chloride containing pyridine<sup>2†</sup> at room temperature or below gave in good yield the corresponding synthetically useful<sup>3</sup> allenyl sulphides (7) from (2) (Scheme 2 and Table), which were converted into their lithium derivatives<sup>4</sup> (8) with *n*-butyl-lithium in tetrahydrofuran (THF) at -80 °C. These reacted readily with a variety of electrophiles, including now epoxides.

For example, the allenyl phenyl sulphide (7b; Ar = Ph) after treatment with *n*-butyl-lithium in THF opened isobutylene oxide to give the alcohol (9b; Ar = Ph) (Scheme 3). Toluene-*p*-sulphonic acid in THF cyclised

SCHEME 3

(9b; Ar = Ph) to (11) which was converted into atlantone<sup>5</sup> (12) (10:1, *trans*:*cis*) with mercuric chloride in wet acetonitrile.<sup>6</sup> However, the yield in the last step was only 35% [accompanied by the diene (13) and 4-acetyl-1-methylcyclohexene (14) from reversed aldol condensations], and several other syntheses were thwarted by the difficulty in hydrolysis of phenylthio-olefins,<sup>7</sup> and -allenes. Of several alternatives to the phenylthio group the *o*- and *p*-methoxyphenylthio<sup>8</sup> were more successful.

Thus treatment of the allenyl sulphide (7b; Ar = *p*-MeOC<sub>6</sub>H<sub>4</sub>) in THF with *n*-butyl-lithium at -80 °C followed by addition of methyl iodide gave the sulphide (9b; Ar = *p*-
