Abstract

The complexes MoX₂(CO)₃(bipy) (X = Cl, Br, I) undergo substitution of a single CO ligand by Ph₂PCH₂PPh₂ (dppm) and Ph₂PCH₂CH₂PPh₂ (dppe) to give seven-coordinate complexes MoX₂(CO)₂(bipy)(L–L) (X = Cl, Br, I; L–L = dppm, dppe). Spontaneous isomerization to [MoX(CO)₂(bipy)(dppm)] X was observed for X = I in dichloromethane at room temperature. However MoCl₂(CO)₂(bipy)(dppm) led to MoCl₂(CO)(bipy)(dppm) by sunlight irradiation. The cationic species [MoX(CO)₂(bipy)(L–L)] BPh₄ (X = Cl, Br; L–L = dppm and X = Cl, Br, I; L–L = dppe) were also prepared by use of NaBPh₄. Reactions of MoX₂(CO)₃(bipy) (X = Cl, Br) with dppe in molar ratios 2/1 (complex/ligand) afforded the slightly soluble compounds formulated as dimers, Mo₂X₄(CO)₄(bipy)₂(μ-dppe). We also report the possibility of preparing MoCl₂(CO)₃(bipy) by direct halogenation of Mo(CO)₄(bipy) at room temperature in dichloromethane.

Introduction

The complexes of Mo(II) and W(II) have received considerable attention recently not only with regard to their reactivity [1] but also for the seven-coordination displayed by these compounds [2, 3]. In a previous paper [4] we have reported several mono and dicarbonyl complexes of Mo(II) containing 2,2'-bipyridyl (bipy) and bis(diphenylphosphino)methane (dppm) as bidentate ligands. In order to further investigate on complexes containing two different bidentate ligands, we have explored in this work the reactions of MoX₂(CO)₃(bipy) (X = Cl, Br, I) with both 1,2-bis(diphenylphosphino)ethane (dppe) and dppm.

Experimental

All preparations were carried out under nitrogen or argon following conventional Schlenk techniques. Solvents were dried and degased before use. The compound Mo(CO)₄(bipy) [5] was prepared as described in the literature. IR spectra were recorded using a Perkin-Elmer 577 spectrophotometer. ³¹P{¹H} NMR spectra were obtained with a Varian FT80A instrument and were measured in CDCl₃ solution at room temperature (δ values to high frequency of external 85% H₃PO₄). Conductivity measurements were made with a WTW conductivity bridge LBR at 3 KHz; the cell constant of the glass conductivity probe was determined by use of 0.01 mol dm⁻³ KCl solution. Elemental analysis for C, H, N were determined with a Carlo Erba 1106 or Perkin-Elmer 240 instrument.

Preparation of MoX₂(CO)₃(bipy) (X = Cl, Br, I)

The procedure was that described by Stiddard [5] for X = Br, I with small modifications.

To a stirred solution of Mo(CO)₄(bipy) (0.4 g, 1.1 mmol) in 90 cm³ of dichloromethane at room temperature was added the stoichiometric amount of X₂ (1.1 mmol) dissolved in carbon tetrachloride. Concentration to ca. 25 cm³ and addition of an equal volume of hexane afforded the solids with yields 85–90%.

Preparation of MoX₂(CO)₂(bipy)(L–L) (L–L = dppm, X = Cl, Br; L–L = dppe, X = Cl, Br, I)

A typical preparation for MoCl₂(CO)₂(bipy)(dppm) is described. To a stirred solution of Mo(CO)₄(bipy) (0.1 g, 0.27 mmol) in 20 cm³ of dichloromethane was added a solution of chlorine in carbon tetrachloride until the formation of MoCl₂(CO)₃(bipy) was completed (IR ν(CO)). To the resulting mixture, dppm (0.104 g, 0.27 mmol) was added and the solution stirred for 10 min. Concentration near to dryness and addition of hexane afforded the solid (0.18 g, 86%). The product was

* Author to whom correspondence should be addressed.

washed with diethylether and recrystallized from CH_2Cl_2 –hexane.

Preparation of $[\text{MoX}(\text{CO})_2(\text{bipy})/(\text{L-L})]\text{BPh}_4$ ($X = \text{Cl, Br, I}$; $\text{L-L} = \text{dppe}$ and $X = \text{Cl, Br}$; $\text{L-L} = \text{dppm}$)

A typical preparation for $[\text{MoI}(\text{CO})_2(\text{bipy})-(\text{dppe})]\text{BPh}_4$ is described. To a solution of $\text{MoI}_2(\text{CO})_2(\text{bipy})(\text{dppe})$ (0.085 g, 0.09 mmol) in 20 cm^3 of dichloromethane was added NaBPh_4 (0.04 g, 0.1 mmol) and the mixture stirred for 4 h. The suspension was filtered and concentrated under vacuum to a half of the volume. Addition of hexane (ca. 20 cm^3) and concentration yielded 0.07 g (68%) of the product.

Preparation of $[\text{MoI}(\text{CO})_2(\text{bipy})/(\text{dppm})]\text{I}$

A solution of $\text{MoI}_2(\text{CO})_3(\text{bipy})$ (0.27 mmol) in 40 cm^3 of dichloromethane was prepared as described above. To this solution was added dppm (0.135 g, 0.35 mmol). After stirring for 8 h the mixture was filtered. Concentration to ca. 15 cm^3 and addition of diethylether afforded the complex as a red powder which was recrystallized from CH_2Cl_2 –hexane. Yield 0.18 g (70%).

Preparation of $\text{MoCl}_2(\text{CO})(\text{bipy})/(\text{dppm})$

The procedure was the same as that used for the bromo-derivative described elsewhere [4].

Preparation of $\text{Mo}_2\text{X}_4(\text{CO})_4(\text{bipy})/(\mu\text{-dppe})$ ($X = \text{Cl, Br}$)

The procedure for the bromo-derivative is described. To a solution of $\text{MoBr}_2(\text{CO})_3(\text{bipy})$ (0.27 mmol) prepared as described above, was added dppe (0.05 g, 0.13 mmol). After stirring for 0.5 h the orange precipitate was washed with hexane and diethylether respectively. Yield 0.1 g (60%).

Results and Discussion

The reactions of $\text{Mo}(\text{CO})_4(\text{bipy})$ with X_2 in chloroform to give $\text{MoX}_2(\text{CO})_3(\text{bipy})$ ($X = \text{Br, I}$) were described by Stiddard [5] in 1962. We have employed the same procedure but dichloromethane was used instead of chloroform. Recently [6] $\text{MoI}_2(\text{CO})_3(\text{bipy})$ has been prepared by treatment of $\text{MoI}_2(\text{CO})_3(\text{NCCH}_3)_2$ with 2,2'-bipyridyl.

The reactions of $\text{Mo}(\text{O})$ carbonyl compounds with chlorine lead in general to a higher oxidation state than $\text{Mo}(\text{II})$ unless low temperatures are used [7, 8]. We have found that it is possible to prepare $\text{MoCl}_2(\text{CO})_3(\text{bipy})$ in good yields by treatment of $\text{Mo}(\text{CO})_4(\text{bipy})$ in dichloromethane with a solution of chlorine in carbon tetrachloride at room temperature. An alternative synthetic route consists in the reaction of $\text{MoCl}_2(\text{CO})_4$ with bipyridine [9], but the

synthesis of $\text{MoCl}_2(\text{CO})_4$ involves the use of low temperatures.

Although it was possible to isolate all the tricarbonyls they were prepared and used 'in situ' by carefully monitoring of the halogenation reaction by IR spectroscopy.

Reactions of $\text{MoX}_2(\text{CO})_3(\text{bipy})$ with dppm

The tricarbonyl $\text{MoCl}_2(\text{CO})_3(\text{bipy})$ reacted with dppm in dichloromethane, in molar ratio 1:1, to give the light sensitive dicarbonyl $\text{MoCl}_2(\text{CO})_2(\text{bipy})-(\text{dppm})$ (1). The $^{31}\text{P}\{^1\text{H}\}$ NMR of 1 in CDCl_3 at room temperature showed two signals at +42 ppm(d) and -27 ppm(d) with $^2J(\text{PP}) = 23$ Hz. These values are similar to the chemical shifts observed for the dppm attached to molybdenum via only one phosphorus ligand [10]. Further reaction of 1 with NaBPh_4 in dichloromethane led to the cationic $[\text{MoCl}(\text{CO})_2(\text{bipy})(\text{dppm})]\text{BPh}_4$ (2). The orange solution of complex 1 in dichloromethane turned slowly dark green when exposed to sunlight at room temperature under nitrogen. This allowed us to isolate the monocarbonyl $\text{MoCl}_2(\text{CO})(\text{bipy})(\text{dppm})$ (3) which underwent further reaction with CO to give $[\text{MoCl}(\text{CO})_2-(\text{bipy})(\text{dppm})]\text{Cl}$ (2a). This complex characterized by IR spectroscopy in solution, was transformed into 2 by treatment with NaBPh_4 .

The same behaviour had been shown by the analogous bromo-derivative [4] but the rate of substitution increased from bromine to chlorine.

The reaction of $\text{MoI}_2(\text{CO})_3(\text{bipy})$ with dppm afforded, in a first step, $\text{MoI}_2(\text{CO})_2(\text{bipy})(\text{dppm})$ which was detected by IR spectroscopy [$\nu(\text{CO})$ bands at 1942 and 1865 cm^{-1}]. However, this compound isomerized into the ionic complex $[\text{MoI}(\text{CO})_2-(\text{bipy})(\text{dppm})]\text{I}$ (4) in dichloromethane solution.

From these results and those reported for the bromo-derivatives [4] it was possible to conclude that the rate of the reactions of $\text{MoX}_2(\text{CO})_3(\text{bipy})$ with dppm to give $\text{MoX}_2(\text{CO})_2(\text{bipy})(\text{dppm})$ increased in the order $\text{I} < \text{Br} < \text{Cl}$. On the contrary, for the isomerization process of $\text{MoX}_2(\text{CO})_2(\text{bipy})(\text{dppm})$ to the ionic complexes $[\text{MoX}(\text{CO})_2(\text{bipy})(\text{dppm})]\text{X}$ the rate increased in the same order, $\text{Cl} < \text{Br} < \text{I}$, as the steric hindrance. For $X = \text{I}$ the ionization occurred spontaneously and for $X = \text{Cl}$ and Br it was necessary to employ NaBPh_4 leading to 2 and $[\text{MoBr}(\text{CO})_2(\text{bipy})(\text{dppm})]\text{BPh}_4$ after stirring at room temperature 20 and 7 h respectively.

The reactions of $\text{MoX}_2(\text{CO})_3(\text{bipy})$ with dppm in molar ratio 2:1 did not afford the dimeric species formed with dppe as discussed below.

Reactions of $\text{MoX}_2(\text{CO})_3(\text{bipy})$ with dppe

Treatment of $\text{MoX}_2(\text{CO})_3(\text{bipy})$ ($X = \text{Cl, Br, I}$) with dppe in molar ratios 1:1 in dichloromethane at room temperature led to the formation of $\text{MoX}_2(\text{CO})_2(\text{bipy})(\text{dppe})$ (5, 6 and 7). These complexes

^aIn dichloromethane solution. ^bIn KBr pellets. ^cIn acetone solution ca. 10⁻³ M.

when exposed to the sunlight, unlike the dppm derivatives, only led to decompositions. However the behaviour of these dicarbonyls with NaBPh₄ was analogous, yielding the cationic [MoX(CO)₂-(bipy)(dppe)] BPh₄ (X = Cl (8), Br (9), I (10)), with rates of substitution increasing in the same order as that for dppm (see below Table II).

The high conductivity exhibited by the neutral dicarbonyls suggested that the equilibrium

was present in acetone solution. In spite of that, the complexes were formulated as neutral because the $\nu(\text{CO})$ frequencies showed lower values than for the ionic compounds (see below Table II).

The reactions of MoX₂(CO)₃(bipy) (X = Cl, Br) with dppe in molar ratios 2:1 allowed us to isolate the complexes [Mo₂X₄(CO)₄(bipy)₂(μ-dppe)] (X = Cl (11), Br (12)). Formulation as dimers was based in their low solubility and elemental analysis. Attempts to carry out molecular weight determinations were always unsuccessful.

The reaction rates with dppe were faster than with dppm due probably to the lower steric hindrance of the dppe [11].

All of the complexes described above were air and light sensitive especially in solution. Yellow or orange solutions in dichloromethane turned purple when they were not conveniently protected. Melting points, analytical data, conductivity and $\nu(\text{CO})$ frequencies for the prepared compounds are given in Tables I and II.
