Received November 24, 2007

The reaction of the group 9 bis(hydrosulfido) complexes $[Cp^*M(SH)_2(PMe_3)]$ (M = Rh, Ir; $Cp^* = \eta^{5-}C_5Me_5$) with the group 6 nitrosyl complexes [Cp*M'Cl₂(NO)] (M' = Mo, W) in the presence of NEt₃ affords a series of bis(sulfido)bridged early-late heterobimetallic (ELHB) complexes $[Cp^*M(PMe_3)(\mu-S)_2M'(NO)Cp^*]$ (2a, M = Rh, M' = Mo; 2b, M = Rh, M' = W; **3a**, M = Ir, M' = Mo; **3b**, M = Ir, M' = W). Similar reactions of the group 10 bis(hydrosulfido) complexes $[M(SH)_2(dppe)]$ (M = Pd, Pt; dppe = Ph₂P(CH₂)₂PPh₂), $[Pt(SH)_2(dppp)]$ (dppp = Ph₂P(CH₂)₃PPh₂), and $[M(SH)_2(dpmb)]$ (dpmb = $o-C_6H_4(CH_2PPh_2)_2$) give the group 10-group 6 ELHB complexes $[(dppe)M(\mu-dph_2)_2)$ S)₂M'(NO)Cp^{*}] (M = Pd, Pt; M' = Mo, W), [(dppp)Pt(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6a**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(NO)Cp^{*}] (**6b**, M' = Mo; **6b**, M' = W), and [(dpmb)M(μ -S)₂M'(M) = Mo; **6b**, M' = Mo; **7b**, M' = Mo; $S_{2}M'(NO)Cp^{*}$ (M = Pd, Pt; M' = Mo, W), respectively. Cyclic voltammetric measurements reveal that these ELHB complexes undergo reversible one-electron oxidation at the group 6 metal center, which is consistent with isolation of the single-electron oxidation products $[Cp^*M(PMe_3)(\mu - S)_2M'(NO)Cp^*][PF_6]$ (M = Rh, Ir; M' = Mo, W). Upon treatment of **2b** and **3b** with ROTf (R = Me, Et; OTf = OSO₂CF₃), the O atom of the terminal nitrosyl ligand is readily alkylated to form the alkoxyimido complexes such as [Cp*Rh(PMe₃)(µ-S)₂W(NOMe)Cp*][OTf]. In contrast, methylation of the Rh-, Ir-, and Pt-Mo complexes 2a, 3a, and 6a results in S-methylation, giving the methanethiolato complexes [Cp*M(PMe₃)(μ -SMe)(μ -S)Mo(NO)Cp*][BPh₄] (M = Rh, Ir) and [(dppp)Pt(μ -SMe)(μ -S)Mo(NO)Cp*][OTf], respectively. The Pt-W complex 6b undergoes either S- or O-methylation to form a mixture of [(dppp)Pt(μ -SMe)(μ -S)W(NO)Cp*][OTf] and [(dppp)Pt(μ -S)₂W(NOMe)Cp*][OTf]. These observations indicate that O-alkylation and one-electron oxidation of the dinuclear nitrosyl complexes are facilitated by a common effect, i.e., donation of electrons from the group 9 or 10 metal center, where the group 9 metals behave as the more effective electron donor.

Introduction

Early-late heterobimetallic (ELHB) complexes in which an electron-deficient early-transition metal and an electronrich late-transition metal are located in close proximity have recently been attracting considerable attention because the cooperative effects between such significantly different metal centers may lead to unique activation and effective transformation of substrate molecules.¹ Yet, it is little understood how early and late metals can interact in actual ELHB complexes, and obviously more information about such cooperative effects is needed to better design effective ELHB systems.² In the course of our study on multinuclear complexes, we have revealed that hydrosulfido complexes serve as versatile metalloligands to construct various ELHB

Heterodinuclear Nitrosyl Complexes

complexes.³ In this study, we have designed group 9– and group 10–group 6 sulfido-bridged nitrosyl complexes [Cp*M-(PMe₃)(μ -S)₂M'(NO)Cp*] (M = Rh, Ir; M' = Mo, W; Cp* = η^{5} -C₅Me₅) and [L₂M(μ -S)₂M'(NO)Cp*] [M = Pd, Pt; M' = Mo, W; L₂ = 1,2-bis(diphenylphosphino)ethane (dppe), 1,2-bis(diphenylphosphino)propane (dppp), *o*-bis(diphenylphosphinomethyl)benzene (dpmb)] and investigated the factors that control the activation of NO at the group 6 metal center.

It is well-known that the nitrosyl ligand exhibits characteristic redox behavior and reactivities depending upon the electronic states of the metal centers.⁴ In particular, the terminally bound linear nitrosyl is an effective π acid and therefore is expected to be activated toward electrophilic attack, but such reactivity has poorly been exploited with actual transition-metal nitrosyl complexes.⁵ On the basis of our previous results on multinuclear nitrosyl complexes,⁶ we have embarked on investigating the origin of the ELHB cooperative effect in nitrosyl activation at dinuclear complexes. In this paper, we report that in the above-mentioned group 9- and group 10-group 6 dinuclear complexes the electron donation from the electron-rich late-transition (group 9 or 10) metal center plays a critical role in the activation of the nitrosyl ligand at the group 6 metal center toward electrophilic O-alkylation. Part of the results have already been published in a Communication.

Experimental Section

General Remarks. All manipulations were carried out under an atmosphere of nitrogen by using standard Schlenk techniques. Dichloromethane (CH_2Cl_2) and 1,2-dichloroethane ($C_2H_4Cl_2$) were

dried and distilled over P_4O_{10} , while NEt₃ was dried and distilled over KOH. The other solvents (dehydrated-grade) were purchased from Aldrich and used as received. [Cp*M(SH)₂(PMe₃)] (M = Rh, Ir),⁸ [Cp*M'Cl₂(NO)] (**1a**, M' = Mo; **1b**, M' = W),⁹ [M(SH)₂-(dppe)] (M = Pd, Pt),¹⁰ [Pt(SH)₂(dppp)],¹¹ and [MCl₂(dpmb)] (M = Pd, Pt)¹² were prepared according to the literature methods. ¹H (500 or 400 MHz) and ³¹P{¹H} (202 or 121 MHz) NMR spectra were recorded on a JEOL ECA-500, JEOL JNM-GSX-400, or Varian Mercury-300 spectrometer by using CDCl₃ as the solvent. IR spectra were recorded on a Jasco FT/IR-410 spectrometer using KBr pellets. Elemental analyses were performed on a Perkin-Elmer 2400II CHN analyzer. Cyclic voltammetry studies were performed with a BAS CV-50W analyzer. Potentials were measured at a glassy-carbon working electrode in a CH₂Cl₂ solution containing 0.1 M (ⁿBu₄N)(BF₄) and a 2 mM sample at 25 °C.

Preparation of $[Cp*M(PMe_3)(\mu-S)_2M'(NO)Cp*]$ (2a, M = Rh, M' = Mo; 2b, M = Rh, M' = W; 3a, M = Ir, M' = Mo; 3b, M = Ir, M' = W). The following procedure for the preparation of [Cp*Rh(PMe₃)(µ-S)₂W(NO)Cp*] (2b) is representative. To a solution of **1b** (475 mg, 1.13 mmol) in THF (40 mL) at -40 °C were added [Cp*Rh(SH)₂(PMe₃)] (430 mg, 1.13 mmol) and NEt₃ (0.33 mL, 2.37 mmol), and the mixture was warmed gradually to room temperature. After 3 h of stirring at room temperature, the dark-brown solution was dried up in vacuo, and the residue was dissolved in CH₂Cl₂ (15 mL) to load onto an alumina column, where the adsorbed mixture was eluted with THF-hexane (2:1). The main green band was collected, and the solvent was removed in vacuo. Recrystallization of the residual dark-green solid from benzene (20 mL)-hexane (45 mL) afforded 2b as dark-green crystals (472 mg, 0.649 mmol, 57% yield). ³¹P{¹H} NMR: δ 7.6 (d, ¹J_{RhP} = 147 Hz, PMe₃). ¹H NMR: δ 1.99 (s, 15H, Cp*W), 1.92 (d, ⁴*J*_{PH} = 2.4 Hz, 15H, Cp*Rh), 1.25 (d, ${}^{2}J_{PH} = 11.0$ Hz, 9H, PMe₃). IR (cm⁻¹): 1490 (v_{NO}). Anal. Calcd for C₂₃H₃₉NOPRhS₂W: C, 37.98; H, 5.40; N, 1.93. Found: C, 38.10; H, 5.45; N, 2.00.

2a: dark-green crystals, 79% yield. ³¹P{¹H} NMR: δ 11.2 (d, ¹J_{RhP} = 147 Hz, PMe₃). ¹H NMR: δ 1.91 (s, 15H, Cp*Mo), 1.89 (d, ⁴J_{PH} = 2.7 Hz, 15H, Cp*Rh), 1.26 (d, ²J_{PH} = 11.0 Hz, 9H, PMe₃). mg, 9.79 mmol) in EtOH (70 mL) and benzene (30 mL) was refluxed for 17 h. The resulting suspension was cooled to room temperature. The precipitate was collected by filtration, washed with H₂O, EtOH, and hexane, and dried in vacuo to afford [Pt(SH)₂(dpmb)] as a white solid (2.23 g, 3.03 mmol, 80% yield). ³¹P{¹H} NMR: δ 1.1 (s with ¹⁹⁵Pt satellites, ¹J_{PtP} = 2928 Hz, dpmb). ¹H NMR: δ 7.85–7.81, 7.48–7.41 (m, total 20H, Ph of dpmb), 7.00, 6.40 (br, 2H each, C₆H₄ of dpmb), 3.94 (d with ¹⁹⁵Pt satellites, ²J_{PH} = 10.0 Hz, ³J_{PtH} = 32.5 Hz, 4H, CH₂ of dpmb), -0.31 (d with ¹⁹⁵Pt satellites, ³J_{PH} = 7.5 Hz, ²J_{PtH} = 49.5 Hz, 2H, SH). Anal. Calcd for C₃₂H₃₀P₂PdS₂: C, 52.24; H, 4.11. Found: C, 51.93; H, 3.97.

[Pd(SH)₂(dpmb)]: yellow solid, 46% yield. ³¹P{¹H} NMR: δ 11.9 (s, dpmb). ¹H NMR: δ 7.80–7.43 (m, 20H, Ph of dpmb), 6.99, 6.39 (br, 2H each, C₆H₄ of dpmb), 3.80 (d, ²*J*_{PH} = 9.0 Hz, 4H, CH₂ of dpmb), -0.30 (d, ³*J*_{PH} = 7.0 Hz, 2H, SH). Anal. Calcd for C₃₂H₃₀P₂PdS₂: C, 59.40; H, 4.67. Found: C, 59.18; H, 4.72.

Preparation of $[(dppe)M(\mu-S)_2M'(NO)Cp^*]$ (4a, M = Pd, M' = Mo; 4b, M = Pd, M' = W; 5a, M = Pt, M' = Mo; 5b,M = Pt, M' = W). The following procedure for the preparation of $[(dppe)Pd(\mu-S)_2Mo(NO)Cp^*]$ (4a) is representative. To a suspension of [Pd(SH)₂(dppe)] (355 mg, 0.62 mmol) in THF (20 mL) at -60 °C were added 1a (206.4 mg, 0.62 mmol) in THF (20 mL) and NEt₃ (0.17 mL, 1.24 mmol), and the mixture was warmed gradually to room temperature with stirring. The dark-brown suspension was stirred overnight and then dried in vacuo. The resultant residue was dissolved in CH2Cl2 and loaded on an alumina column. The main brown band eluted with CH₂Cl₂-MeOH (100: 2) was collected, and the volatile materials were removed in vacuo. Recrystallization of the residual dark-brown solid from CH₂Cl₂-hexane afforded 4a·CH₂Cl₂ as brown crystals (294 mg, 0.32 mmol, 52% yield). ³¹P{¹H} NMR: δ 60.3 (s, dppe). ¹H NMR: δ 7.78–7.41 (m, 20H, Ph of dppe), 2.45 (br, 4H, CH₂ of dppe), 1.79 (s, 15H, Cp*). IR (cm⁻¹): 1535 (ν_{NO}). Anal. Calcd for C37H41Cl2MoNOP2PdS2: C, 48.56; H, 4.52; N, 1.53. Found: C, 48.62; H, 4.54; N, 1.50.

4b•C₂H₄Cl₂: recrystallized from C₂H₄Cl₂-hexane, dark-purple crystals, 63% yield. ³¹P{¹H} NMR: δ 55.3 (s, dppe). ¹H NMR: δ 7.78–7.41 (m, 20H, Ph of dppe), 2.45 (br, 4H, CH₂ of dppe), 1.79 (s, 15H, Cp*). IR (cm⁻¹): 1499 (ν_{NO}). Anal. Calcd for C₃₈H₄₃Cl₂NOP₂PdS₂W: C, 44.88; H, 4.26; N, 1.38. Found: C, 44.68; H, 4.28; N, 1.36.

5a•CH₂Cl₂: eluted with CH₂Cl₂-MeOH (100:1), light-green crystals, 70% yield. ³¹P{¹H} NMR: δ 50.4 (s with ¹⁹⁵Pt satellites, ¹*J*_{PtP} = 3116 Hz, dppe). ¹H NMR: δ 7.78-7.41 (m, 20H, Ph of dppe), 2.41 (br, 4H, CH₂ of dppe), 1.79 (s, 15H, Cp*). IR (cm⁻¹): 1534 (ν_{NO}). Anal. Calcd for C₃₇H₄₁Cl₂MoNOP₂PtS₂: C, 44.27; H, 4.12; N, 1.40. Found: C, 44.10; H, 4.15; N, 1.37.

5b•C₂H₄Cl₂: recrystallized from C₂H₄Cl₂-hexane, brown crystals, 46% yield. ³¹P{¹H} NMR: δ 46.4 (s with ¹⁹⁵Pt satellites, ¹*J*_{PtP} = 3194 Hz, dppe). ¹H NMR: δ 7.76–7.43 (m, 20H, Ph of dppe), 2.45 (br, 4H, CH₂ of dppe), 1.85 (s, 15H, Cp*). IR (cm⁻¹): 1497 (ν_{NO}). Anal. Calcd for C₃₈H₄₃Cl₂NOP₂PtS₂W: C, 41.28; H, 3.92; N, 1.27. Found: C, 41.19; H, 3.97; N, 1.27.

Preparation of [(dppp)Pt(μ-S)₂M'(NO)Cp*] (6a, M' = Mo; 6b, M' = W). These complexes were synthesized from [Pt(SH)₂(dppp)] and **1a** or **1b** by a procedure similar to that described for **4a** except that CH₂Cl₂ was used as the eluent for alumina column chromatography. **6a**: green solids, 83% yield. ³¹P{¹H} NMR: δ -4.0 (s with ¹⁹⁵Pt satellites, ¹J_{PtP} = 3056 Hz, dppp). ¹H NMR: δ 7.65-7.37 (m, 20H, Ph of dppp), 2.61-2.53 (br, 4H, CH₂ of dppp), 2.14-1.84 (br, 2H, CH₂ of dppp), 1.63 (s, 15H, Cp*). IR (cm⁻¹): 1535 (ν_{NO}). Anal. Calcd for C₃₇H₄₁-MoNOP₂PtS₂: C, 47.64; H, 4.43; N, 1.50. Found: C, 47.88; H, 4.43; N, 1.45.

6b: brown solids, 56% yield. ³¹P{¹H} NMR: δ -8.5 (s with ¹⁹⁵Pt satellites, ¹*J*_{PtP} = 3125 Hz, dppp). ¹H NMR: δ 7.63-7.35 (m, 20H, Ph of dppp), 2.66-2.51 (br, 4H, CH₂ of dppp), 2.12-1.88 (br, 2H, CH₂ of dppp), 1.78 (s, 15H, Cp*). IR (cm⁻¹): 1499 (ν_{NO}). Anal. Calcd for C₃₇H₄₁NOP₂PtS₂W: C, 43.54; H, 4.05; N, 1.37. Found: C, 43.65; H, 4.08; N, 1.30.

Preparation of [(dpmb)M(μ -S)₂M'(NO)Cp*] (7a, M = Pd, M' = Mo; 7b, M = Pd, M' = W; 8a, M = Pt, M' = Mo; 8b, M = Pt, M' = W). These complexes were obtained from [M(SH)₂(dpmb)] (M = Pd, Pt) by a procedure similar to that described for 4a. 7a · Et₂O · 0.5CH₂Cl₂: eluted with CH₂Cl₂, brown crystals, 52% yield. ³¹P{¹H} NMR: δ 7.8 (s, dpmb). ¹H NMR: δ 7.92-7.41 (m, 20H, Ph of dpmb), 6.72, 5.99 (m, 2H each, C₆H₄ of dpmb), 4.35, 3.67 (m, 2H each, CH₂ of dpmb), 1.39 (s, 15H, Cp*. IR (cm⁻¹): 1525 (ν_{NO}). Anal. Calcd for C_{46.5}H₅₄ClMoNO₂P₂PdS₂: C, 54.60; H, 5.32; N, 1.37. Found: C, 54.86; H, 5.31; N, 1.36.

7b•CH₂Cl₂: eluted with CH₂Cl₂-MeOH (100:2), dark-blue crystals, 76% yield. ³¹P{¹H} NMR: δ 3.3 (s, dpmb). ¹H NMR: δ 7.94-7.40 (m, 20H, Ph of dpmb), 6.70, 5.97 (m, 2H each, C₆H₄ of dpmb), 4.32, 3.66 (m, 2H each, CH₂ of dpmb), 1.43 (s, 15H, Cp*). IR (cm⁻¹): 1482 (ν_{NO}). Anal. Calcd for C₄₃H₄₅Cl₂NOP₂PdS₂W: C, 47.86; H, 4.20; N, 1.30. Found: C, 47.88; H, 4.20; N, 1.30. Crystals of **7b**•MeCN suitable for X-ray analysis were obtained by further recrystallization from MeCN-Et₂O.

8a•Et₂O•0.5CH₂Cl₂: eluted with CH₂Cl₂-MeOH (100:2), green crystals, 58% yield. ³¹P{¹H} NMR: δ 0.3 (s with ¹⁹⁵Pt satellites, ¹*J*_{PtP} = 3266 Hz, dpmb). ¹H NMR: δ 7.89-7.42 (m, 20H, Ph of dpmb), 6.74, 6.04 (m, 2H each, C₆H₄ of dpmb), 4.31, 3.91 (m, 2H each, CH₂ of dpmb), 1.42 (s, 15H, Cp*). 10b: dark-green crystals, 97% yield. IR (cm⁻¹): 1578 (ν_{NO}). Anal. Calcd for C₂₃H₃₉F₆IrNOP₂S₂W: C, 28.73; H, 4.09; N, 1.46. Found: C, 28.91; H, 4.03; N, 1.30.

Heterodinuclear Nitrosyl Complexes

Preparation of [Cp*M(PMe₃)(µ-S)₂W(NOR)Cp*][OTf] (11, M = Rh, R = Me; 12, M = Ir, R = Me; 13, M = Rh, R =Et; 14, M = Ir, R = Et). The following procedure for the preparation of [Cp*Rh(PMe₃)(µ-S)₂W(NOMe)Cp*][OTf] (11; OTf = OSO_2CF_3) is representative. To a dark-green solution of **2b** (160 mg, 0.220 mmol) in CH₂Cl₂ (10 mL) was added MeOTf (25 μ L, 0.22 mmol) at -40 °C, and the resultant red solution was gradually warmed to room temperature. The solution was stirred overnight and dried in vacuo. The dark-red residue was recrystallized from CH₂Cl₂-hexane (5 mL-10 mL) to afford 11 as a red solid (179 mg, 0.201 mmol, 91% yield). ³¹P{¹H} NMR: δ 8.1 (d, ¹J_{RhP} = 142 Hz, PMe₃). ¹H NMR: δ 4.06 (s, 3H, NOMe), 2.18 (s, 15H, Cp*W), 1.93 (d, ${}^{4}J_{PH} = 2.9$ Hz, 15H, Cp*Rh), 1.31 (d, ${}^{2}J_{PH} = 11.2$ Hz, 9H, PMe₃). Anal. Calcd for C₂₅H₄₂F₃NO₄PRhS₃W: C, 33.68; H, 4.75; N, 1.57. Found: C, 33.50; H, 4.81; N, 1.54. Single crystals of $[Cp*Rh(PMe_3)(\mu-S)_2W(NOMe)Cp*][PF_6]$ (11') suitable for X-ray crystallography were obtained by the anion metathesis of 11 with ⁿBu₄NPF₆ and further recrystallization from CH₂Cl₂-hexane.

12: orange crystals, 95% yield. ${}^{31}P{}^{1}H$ NMR: $\delta -25.3$ (s, PMe₃). ${}^{1}H$ NMR: $\delta 4.02$ (s, 3H, NOMe), 2.20 (s, 15H, Cp*W), 1.94 (d, ${}^{4}J_{PH} = 1.2$ Hz, 15H, Cp*Ir), 1.41 (d, ${}^{2}J_{PH} = 11.2$ Hz, 9H, PMe₃). Anal. Calcd for C₂₅H₄₂F₃IrNO₄PS₃W: C, 30.61; H, 4.32; N, 1.43. Found: C, 30.37; H, 4.32; N, 1.50.

13: red crystals, 53% yield. ³¹P{¹H} NMR: δ 9.3 (d, ¹*J*_{RhP} = 143 Hz, PMe₃). ¹H NMR: δ 4.27 (q, ³*J*_{HH} = 6.4 Hz, 2H, NOC*H*₂CH₃), 2.16 (s, 15H, Cp*W), 1.92 (d, ⁴*J*_{PH} = 2.7 Hz, 15H, Cp*Rh), 1.30 (m, 12H, PMe₃ and NOCH₂C*H*₃). Anal. Calcd for C₂₆H₄₄F₃NO₄PRhS₃W: C, 34.49; H, 4.90; N, 1.55. Found: C, 34.44; H, 5.01; N, 1.52.

14: brown crystals, 84% yield. ${}^{31}P{}^{1}H{}$ NMR: $\delta - 25.5$ (s, PMe₃). ${}^{1}H$ NMR: δ 4.21 (q, ${}^{3}J_{HH} = 7.0$ Hz, 2H, NOCH₂CH₃), 2.16 (s, 15H, Cp*W), 1.91 (d, ${}^{4}J_{PH} = 1.0$ Hz, 15H, Cp*Ir), 1.37 (d, ${}^{2}J_{PH} =$ 11.0 Hz, 9H, PMe₃), 1.26 (t, ${}^{3}J_{HH} = 7.0$ Hz, 3H, NOCH₂CH₃). Anal. Calcd for C₂₆H₄₄F₃IrNO₄PS₃W: C, 31.39; H, 4.46; N, 1.41. Found: C, 31.00; H, 4.34; N, 1.38.

Preparation of [Cp*M(PMe₃)(µ-SMe)(µ-S)Mo(NO)Cp*]- $[BPh_4]$ (15, M = Rh; 16, M = Ir). The following procedure for the preparation of [Cp*Rh(PMe₃)(µ-SMe)(µ-S)Mo(NO)Cp*][BPh₄] (15) is representative. To a dark-green solution of 2a (37 mg, 0.058 mmol) in CH₂Cl₂ (5 mL) was added MeOTf (6.6 µL, 0.058 mmol) at -40 °C, and the mixture was stirred at room temperature for 5 h. The resultant dark-red solution was evaporated to dryness, and NaBPh₄ (ca. 20 mg) and CH₂Cl₂ (5 mL) were added to the residual solid. The mixture was filtered, and Et₂O (10 mL) was added to the concentrated filtrate (4 mL). Dark-red crystals of 15 were gradually formed upon standing at room temperature for 2 weeks, which were collected by filtration and washed with hexane (30.0 mg, 0.031 mmol, 53% yield). ³¹P{¹H} NMR: δ 12.5 (d, ¹J_{RhP} = 135 Hz, PMe₃). ¹H NMR: δ 2.58 (s, 3H, SMe), 1.90 (s, 15H, Cp*Mo), 1.74 (d, ${}^{4}J_{PH} = 3.2$ Hz, 15H, Cp*Rh), 0.94 (d, ${}^{2}J_{PH} =$ 11.5 Hz, 9H, PMe₃). IR (cm⁻¹): 1573 (ν_{NO}). Anal. Calcd for C₄₈H₆₂BMoNOPRhS₂: C, 59.20; H, 6.42; N, 1.44. Found: C, 59.07; H, 6.48; N, 1.39.

16: brown crystals, 54% yield. ³¹P{¹H} NMR: δ –24.4 (s, PMe₃). ¹H NMR: δ 2.68 (s, 3H, SMe), 2.01 (d, ⁴*J*_{PH} = 1.5 Hz, 15H, Cp*Ir), 1.93 (s, 15H, Cp*Mo), 1.36 (d, ²*J*_{PH} = 11.5 Hz, 9H, PMe₃). IR (cm⁻¹): 1572 (*ν*_{NO}). Anal. Calcd for C₄₈H₆₂BIrMoNOPS₂: C, 54.23; H, 5.88; N, 1.32. Found: C, 54.20; H, 6.24; N, 1.20.

Preparation of $[(dppp)Pt(\mu-SMe)(\mu-S)Mo(NO)Cp*][OTf] \cdot CH_2Cl_2$ (17 · CH_2Cl_2). MeOTf (8.0 mg, 0.049 mmol) was added to a solution of **6a** (42.0 mg, 0.045 mmol) in CH₂Cl₂ (5 mL) at -60 °C. The mixture was stirred overnight at room temperature, and then the volatiles were removed in vacuo. The brown residue

was recrystallized from CH₂Cl₂-hexane to afford **17**•CH₂Cl₂ as orange crystals (40.0 mg, 0.034 mmol, 75%). ³¹P{¹H} NMR: δ -9.1 (d with ¹⁹⁵Pt satellites, $J_{PP} = 32$ Hz, ¹ $J_{PtP} = 3054$ Hz, dppp), -13.6 (d with ¹⁹⁵Pt satellites, $J_{PP} = 32$ Hz, ¹ $J_{PtP} = 2884$ Hz, dppp). ¹H NMR: δ 7.68–7.29 (m, 20H, Ph of dppp), 3.53–3.45, 3.29–3.22 (m, 1H each, CH₂ of dppp), 2.90–2.81 (m, 2H, CH₂ of dppp), 2.63–2.50 (br, 2H, CH₂ of dppp), 2.22 (d with ¹⁹⁵Pt satellites, ⁴ $J_{PH} = 3.5$ Hz, ³ $J_{PtH} = 34.0$ Hz, 3H, SMe), 1.76 (s, 15H, Cp*). IR (cm⁻¹): 1603 (ν_{NO}). Anal. Calcd for C₄₀H₄₆Cl₂F₃MoNO₄P₂PtS₃: C, 40.65; H, 3.92; N, 1.19. Found: C, 40.51; H, 3.87; N, 1.13.

Reaction of 6b with MeOTf. MeOTf (1 equiv) was added to a solution of **6b** in CH₂Cl₂ at -60 °C to afford a mixture of the S-methylated complex [(dppp)Pt(μ -SMe)(μ -S)W(NO)Cp*](OTf) (**18**) and the O-methylated complex [(dppp)Pt(μ -S)₂W(NOMe)-Cp*](OTf) (**19**) (ca. 2:1, determined by ³¹P{¹H} and ¹H NMR). These complexes could not be separated but were characterized spectroscopically.

18. ${}^{31}P{}^{1}H$ NMR: $\delta -9.4$ (d with ${}^{195}Pt$ satellites, $J_{PP} = 30$ Hz, ${}^{1}J_{PtP} = 3098$ Hz, dppp), -13.8 (d with ${}^{195}Pt$ satellites, $J_{PP} = 30$ Hz, ${}^{1}J_{PtP} = 2970$ Hz, dppp). ${}^{1}H$ NMR: $\delta 2.36$ (br, 3H, SMe), 1.86 (s, 15H, Cp*). IR (cm⁻¹): 1602 (ν_{NO}).

19. ³¹P{¹H} NMR: δ -8.9 (s with ¹⁹⁵Pt satellites, ¹*J*_{PtP} = 3088 Hz, dppp). ¹H NMR: δ 3.77 (s, 3H, NOMe), 1.93 (s, 15H, Cp*).

Preparation of [Cp*M(PMe₃)(µ-S)₂W(O)Cp*](OTf) (20, M = **Rh**; 21, **M** = **Ir**). The following procedure for the preparation of [Cp*Rh(PMe₃)(µ-S)₂W(O)Cp*][OTf] (20) is representative. To a dark-green solution of 2b (53.0 mg, 0.073 mmol) in CH₂Cl₂ (5 mL) was added HOTf (13 μ L, 0.15 mmol) at -40 °C, and the resultant red solution was gradually warmed to room temperature. The solution was stirred overnight and was dried in vacuo. The residual red oil was recrystallized from CH2Cl2 (2 mL)-Et2O (20 mL) to afford 20 as orange needles (47.3 mg, 0.055 mmol, 75% yield). ³¹P{¹H} NMR: δ 8.7 (d, ¹*J*_{RhP} = 140 Hz, PMe₃). ¹H NMR: δ 2.22 (s, 15H, Cp*W), 2.00 (d, ${}^{4}J_{PH} = 2.5$ Hz, 15H, Cp*Rh), 1.39 (d, ${}^{2}J_{\text{PH}} = 11.5 \text{ Hz}$, 9H, PMe₃). IR (cm⁻¹): 909 ($\nu_{\text{W=O}}$). Anal. Calcd for C₂₄H₃₉F₃O₄PRhS₃W: C, 33.42; H, 4.56. Found: C, 33.40; H, 4.60. Single crystals of $[Cp*Rh(PMe_3)(\mu-S)_2W(O)Cp*][BPh_4]$ (20') suitable for X-ray crystallography were obtained by the anion metathesis of 20 with NaBPh₄ and further recrystallization from CH₂Cl₂-Et₂O.

21: yellow needles, 51% yield. ³¹P{¹H} NMR: δ -22.7 (s, PMe₃). ¹H NMR: δ 2.23 (s, 15H, Cp*W), 2.02 (d, ⁴*J*_{PH} = 1.5 Hz, 15H, Cp*Ir), 1.46 (d, ²*J*_{PH} = 11.5 Hz, 9H, PMe₃). IR (cm⁻¹): 910 (ν _{W=O}). Anal. Calcd for C₂₄H₃₉F₃IrO₄PS₃W: C, 30.29; H, 4.13. Found: C, 30.13; H, 4.02.

Magnetic Moment Measurements. The ambient-temperature solution magnetic moment of **9b** was measured by the Evans method.¹³ A CD₂Cl₂ solution of **9b** with known concentration (6.8 mM) was prepared and placed in an NMR tube. A ¹H NMR spectrum was first recorded, and then a coaxial reference capillary filled with pure CD₂Cl₂ was inserted inside the sample tube. A second ¹H NMR spectrum, which clearly showed the original and the paramagnetically shifted deuterated solvent peaks, was thus obtained. The magnetic moment was calculated using equations and parameters cited in ref 14.

X-ray Diffraction Studies. Diffraction data for **2b**, **4a** • CH₂Cl₂, **9b**, **11'**, **15**, and **20'** were collected on a Rigaku AFC-7S four-

circle automated diffractometer (crystal-to-detector distance 235 mm) with graphite-monochromated Mo K α radiation ($\lambda = 0.710$ 69 Å) at room temperature using the $\omega - 2\theta$ scan technique. Diffraction data for 6a and 7b · MeCN were collected on a Rigaku Mercury CCD area detector (crystal-to-detector distance 45 mm) with graphite-monochromated Mo K α radiation ($\lambda = 0.710$ 69 Å) at -150 °C. Cell parameters were determined by least-squares refinement of 25 machine-centered reflections for 2b, 4a · CH₂Cl₂, 9b, 11', 15, and 20' or of reflections among $5 < 2\theta < 55^{\circ}$ for 6a and 7b · MeCN. Intensity data were corrected for empirical absorptions (Ψ scans for 2b, 4a·CH₂Cl₂, 9b, 11', 15, and 20'; REQAB for **6a** and **7b**·MeCN) and for Lorentz-polarization effects.¹⁵ A correction for secondary extinction was further applied for 2b [coefficient, 32(5)], 4a · CH₂Cl₂ [coefficient, 57(8)], 9b [coefficient, 35(4)], **11'** [coefficient, 52(2)], and **20'** [coefficient, 16(2)].¹⁶ No significant decay was observed during the collection of reflections. The structure solution and refinements were carried out using the CrystalStructure crystallographic software package.¹⁷ The positions of the heavy atoms were determined by direct methods (SIR92 for 7b·MeCN; SHELX97 for 20')¹⁸ or by Patterson methods (PATTY

for **2b**, **4a**•CH₂Cl₂, **9b**, **11'**, and **15**; *SHELX-97* for **6a**),¹⁹ and the remaining non-H atoms were found by subsequent Fourier syntheses.²⁰ All non-H atoms were refined on F_0 [$I > 3\sigma(I)$] anisotropically by full-matrix least-squares techniques, while all the H atoms were placed at calculated positions with fixed isotropic parameters. The atomic scattering factors were taken from ref 21. Anomalous dispersion effects were included in F_c .²² The values of $\Delta f'$ and $\Delta f''$ were taken from ref 23. Details of the X-ray diffraction study are summarized in Tables 1 and 2.

Results and Discussion

Synthesis and Structure of Group 9–Group 6 Heterodinuclear Complexes 2 and 3. When the bis(hydrosulfido) complexes of the group 9 metals $[Cp*M(SH)_2(PMe_3)]$ (M = Rh, Ir) were allowed to react with an equimolar amount of the group 6 nitrosyl complexes $[Cp*M'Cl_2(NO)]$ (1) in the presence of 2 equiv of NEt₃, the bis(sulfido)-bridged ELHB complexes $[Cp*M(PMe_3)(\mu-S)_2M'(NO)Cp*]$ (2 and 3) were obtained in good-to-moderate yields (eq 1). The molybdenum complexes 2a and 3a show one strong IR

absorption assignable to the NO stretching around 1520 cm⁻¹ and the tungsten congeners **2b** and **3b** at 1490 cm⁻¹. These ν (NO) values are among the lowest for linear nitrosyl complexes and suggest the existence of strong M' \rightarrow NO backbonding.²⁴ Particularly noteworthy is the large red shift from the mononuclear thiolato complexes [Cp*M'(NO)(SPh)₂] [ν (NO) = 1631 (M' = Mo), 1609 (M' = W) cm⁻¹],²⁵ which mimic the coordination environment of **2** and **3** except for the neighboring rhodium or iridium center. We thus attribute the strong π back-bonding primarily to the influx of electrons from the group 9 metal center through the M^{III} \rightarrow M'^{II} dative bond.²⁶ The ¹H NMR spectra display a set of signals due to two distinct Cp* ligands and one PMe₃ ligand, being well in accordance with the formulation.

The molecular structure of **2b** has been established by an X-ray diffraction study (Table 3). The unit cell contains two independent but very similar complex molecules, one of which is shown in Figure 1. Both rhodium and tungsten centers adopt a three-legged piano-stool geometry. The two Cp* ligands occupy mutually trans positions with respect to the RhWS₂ ring. Within the RhWS₂ core, the short Rh–W distance (2.91 Å, mean) as well as the acute Rh–S–W angles (75.9°, mean) clearly indicates the presence of a dative bond from Rh^{III} to W^{II} in agreement with the 34e structure

of **2b**. As mentioned above, this electron donation between the metal atoms is responsible for the electron-rich nature of the W^{II} center. Enhancement of the π donation of the bridging S atoms by the Rh atom is not evident, because the

- (24) (a) Hayton, T. W.; Legzdins, P.; Patrick, B. O. *Inorg. Chem.* 2002, 41, 5388–5396. (b) Müller, A.; Eltzner, W.; Clegg, W.; Sheldrick, G. M. *Angew. Chem., Int. Ed. Engl.* 1982, 21, 536–537. (c) Chen, Z.; Schmalle, H. W.; Fox, T.; Berke, H. *Dalton Trans.* 2005, 580–587.
- (25) Jin, G.-X.; Herberhold, M. Transition Met. Chem. 2001, 26, 445-447.
- (26) In complexes 2 and 3, the π donation from the S atoms to the molybdenum/tungsten center is considered to be stronger than that in $[Cp*M'(NO)(SPh)_2]$ (M' = Mo, W) because of the four-electron repulsion from the 18e rhodium/iridium center, and this effect may also be responsible to the low ν_{NO} values of 2 and 3 (see ref 27). However, as described below, the W-S bond distances in 2b are not as exceptional as 16e W^{II}-S bonds. Therefore, we believe that the Rh/Ir \rightarrow Mo/W dative bond plays the major role in the increase of the electron density at the Mo/W center.
- (27) (a) Fox, D. C.; Fiedler, A. T.; Halfen, H. L.; Brunold, T. C.; Halfen, J. A. J. Am. Chem. Soc. 2004, 126, 7627–7638. (b) Galindo, A.; Mealli, C.; Cuyás, J.; Miguel, D.; Riera, V.; Pérez-Martínez, J. A.; Bois, C.; Jeannin, Y. Organometallics 1996, 15, 2735–2744.

W–S distances in **2b** (2.33 Å) are comparable with those in the related mononuclear polysulfido complex [Cp*W-(NO)(S₅)] (2.33 Å).²⁸ It should also be mentioned that the two W–C bonds trans to the nitrosyl ligand (2.53–2.55 Å) are meaningfully longer than the other three W–C bonds (2.34–2.37 Å), although the Cp* protons are indistinguishable in the ¹H NMR spectrum even at –90 °C. We consider that the increased electron density of the tungsten center, in combination with the trans influence of the nitrosyl ligand,²⁹ causes the displacement of the Cp* ligand on the W atom from the symmetrical η^5 -coordination.³⁰ Despite the electron richness of the tungsten center and the consequent strong π back-donation, the structure of the W–N–O moiety is not exceptional as a linear nitrosyl ligand.

Synthesis and Structure of Group 10–Group 6 Heterodinuclear Complexes 4–8. When the group 10 bis(hydrosulfido) complexes $[L_2M(SH)_2]$ ($L_2 = dppe$, dppp, dpmb; M = Pd, Pt) were used as templates to react with 1, a series of group 10–group 6 ELHB complexes $[(dppe)M(\mu-S)_2M'(NO)Cp^*]$ (4 and 5), $[(dppp)Pt(\mu-S)_2M'(NO)Cp^*]$ (6), and $[(dpmb)M(\mu-S)_2M'(NO)Cp^*]$ (7 and 8) were obtained in good-to-moderate yields (eq 2). In the IR spectra, an NO stretching is observed at around 1530 cm⁻¹ for the molybdenum complexes 4a–8a and 1500 cm⁻¹ for the tungsten complexes 4b–8b. The lowest ν_{NO} values are observed for M(dpmb)-W complexes 7b and 8b at around 1480 cm⁻¹ (overlapping with a ν_{PPh} band). The ¹H and ³¹P{¹H} NMR spectra of 4–8 are consistent with the formulation and indicative of a C_s symmetrical structure.

The detailed molecular structure of **4a** has been determined by X-ray crystallography (Figure 2 and Table 4). The unit cell contains two crystallographically independent molecules, but their structures are essentially the same. The Pd atom has a square-planar geometry, and the PdMoS₂ core is slightly puckered where the dihedral angle between the PdS₂ and MoS₂ planes is 165.3°. On the other

hand, the structure of the molybdenum center is closely related to that of the tungsten center in **2b** except that the displacement of the Cp* ligand from η^5 coordination is not as remarkable as that in **2b**. The separation of Pd–Mo (2.91 Å, mean) and the acute angle of Pd–S–Mo (76.9°, mean) suggest the presence of a dative bond from Pd^{II} to Mo^{II}.

The molecular structures of (dppp)Pt–Mo complex **6a** and (dpmb)Pd–W complex **7b** were also confirmed by crystallographic studies (Figure 3 and Table 5). Complex **7b** has a crystallographic mirror plane containing the Pd1, W1, N1, O1, and C3 atoms. The total coordination geometries of **6a** and **7b** are similar to that of **4a**, but the difference in the phosphine chelate ring size gives rise to the slight deformation of the core structure. Unlike **4a**, the PtMoS₂ atoms in **6a** are almost coplanar, while the P₂S₂ coordination arrangement around the platinum center is distorted from planarity, where the PtP₂ plane is skewed by 13.9° from the PtS₂ plane. On the other hand, the palladium center in **7b** adopts almost a planar geometry, while the PdWS₂ core is considerably puckered (159.1°). In all cases, the nitrosyl ligands keep the linear coordination mode.

Electrochemical Properties of 2-8. The electron-rich nature of the group 6 metal centers in 2-8 was further demonstrated by cyclic voltammetry measurements. As shown in Table 6, complexes 2-8 undergo reversible single-electron oxidations. The dinuclear complexes containing molybdenum are oxidized at 0.22-0.24 V (for the group 9 metal complexes) or 0.37-0.41 V (for the group 10 metal complexes) vs SCE and those containing tungsten at 0.12-0.13 V (for the group 9 metal complexes) or 0.29-0.31 V (for the group 10 metal complexes). Because the potentials are governed by the group 6 metals regardless of the group 9 and 10 metals, the oxidation could be ascribed mainly to

^a vs SCE, reversible.

that of the group 6 metal center. The chelate size of the diphosphine in complexes 4-8 has little effect on the oxidation potentials. No notable reduction waves are observed in the range down to -1.5 V. These results make a sharp contrast with the redox behavior of the parent mononuclear group 6 nitrosyl complexes $[Cp*M'X_2(NO)]$ (M' = Mo, X = Cl, Br, I; M' = W, X = I), for which a reversible single-electron reduction at -0.3 to -0.5 V has been reported.31 In the present ELHB complexes, the flux of electrons from the neighboring late metal center obviously increases the electron density at the group 6 metal center and facilitates its oxidation. It is also interesting to note that the group 9-group 6 complexes 2 and 3 are oxidized at lower potentials by about 0.17 V than the group 10-group 6 complexes 4-8 in spite of the lower oxidation state of the group 10 metals. We consider that the formal 18e structure of the Rh^{III}/Ir^{III} center in 2 and 3 contributes to the more effective electron donation than the formal 16e PdII/PtII center in 4-8.

One-Electron Oxidation of 2 and 3. On the basis of the electrochemical behavior of 2-8, we next examined isolation of the one-electron-oxidation products. Treatment of **2** and **3** with [Cp₂Fe][PF₆] afforded the cationic complexes [Cp*M-(PMe₃)(μ -S)₂M'(NO)Cp*][PF₆] (**9** and **10**) in excellent yield (eq 3). Extremely broadened ¹H NMR spectra clearly indicate the paramagnetic nature of **9** and **10**. Complex **9b** exhibits

 $\mu_{\rm eff} = 1.87$ (Evans NMR method), which is consistent with an $S = \frac{1}{2}$ system. In good agreement with the oxidation of the group 6 metal center, 9 and 10 exhibit an NO stretching band at around 1595 cm⁻¹ (molybdenum complexes) or 1580 cm⁻¹ (tungsten complexes), which is about 100 cm⁻¹ blueshifted compared to those for 2 and 3. The molecular structure of 9b was fully established by an X-ray analysis (Figure 4 and Table 7). The Rh–W [2.8833(6) Å] and W–S (2.28 Å, mean) bond distances are slightly shorter than those of 2b, suggesting oxidation of the tungsten center. On the other hand, the Cp* ligand at the tungsten center adopts a normal η^5 -coordination mode with the approximately equivalent W-C distances (2.36-2.40 Å), which is also consistent with the lower electron density at the W atom than in 2b. In contrast to 2 and 3, oxidation of 4-8 with [Cp₂Fe][PF₆] resulted in unidentified complex mixtures.

Alkylation of Complexes 2 and 3. As described above, complexes 2–8 are featured by the strong π back-bonding to the nitrosyl ligand. We have therefore examined their reactivities with electrophiles. As expected, treatment of the M–W complex 2b or 3b with 1 equiv of ROTf (R = Me, Et; OTf = OSO₂CF₃) in CH₂Cl₂ selectively afforded the M^{III}/ W^{VI} alkoxyimido complexes [Cp*M(PMe₃)(μ -S)₂W(NOR)-Cp*](OTf) (11–14) through the electrophilic O-alkylation of the nitrosyl ligand (eq 4). These complexes have been

Figure 5. Molecular structure of the cationic part of **11**'. Thermal ellipsoids are shown at the 50% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (deg): W1–Rh1 2.9096(3), W1–S1 2.297(1), W1–S2 2.303(1), W1–N1 1.747(4), Rh1–S1 2.388(1), Rh1–S2 2.398(1), N1–O1 1.350(6), O1–C11 1.436(7), W1–S1–Rh1 76.74(4), W1–S2–Rh1 76.46(4), W1–N1–O1 164.0(3), N1–O1–C11 112.3(4).

characterized by the absence of IR absorptions ascribable to the NO multiple bond and a new ¹H NMR resonance for the alkoxy group. The detailed structure of [Cp*Rh(PMe₃)(µ- $S_{2}W(NOMe)Cp^{*}(PF_{6})$ (11'), which is obtained by the anion metathesis of 11 with [Bu₄N][PF₆], has been unambiguously determined by an X-ray crystallographic study (Figure 5). The W–N–O moiety is essentially linear $[164.0(3)^{\circ}]$, being diagnostic of the four-electron donor character of the alkoxyimido ligand. The metrical parameters of the alkoxyimido ligand in 11' are comparable to those in [CpNbCl₂(NOBu^t)], which was derived from an O-tertbutylhydroxylamine salt.32 It should be mentioned that electrophilic methylation of a genuine terminal nitrosyl ligand has not been described in the literature. The closest example to the present reaction is the methylation of the anionic nitrosyl complex [Cp*MoMe₃(NO)Li(thf)₂]₂, giving the methoxyimido complex [Cp*MoMe₃(NOMe)].³³ The Mo-N-O-Li array in the former lithiated complex, however, has been revealed to be a bridging oxoimido ligand on the basis of X-ray crystallography [Mo-N, 1.742(2) Å; N-O, 1.279(3) Å] and IR spectroscopy ($\nu_{\rm NO} = 1399 \text{ cm}^{-1}$). On the other hand, the μ -NO ligands are known to be more activated toward electrophilic attack, and several examples of their methylation have been documented.³⁴

In contrast to the O-alkylation of **2b** and **3b**, treatment of the M–Mo complexes **2a** and **3a** with MeOTf followed by

the anion metathesis with NaBPh₄ resulted in selective formation of the methanethiolato complexes [Cp*M(PMe₃)(µ-SMe)(μ -S)Mo(NO)Cp*][BPh₄] (**15** and **16**; Scheme 1).³⁵ Complex 15 exhibits a $v_{\rm NO}$ band at 1573 cm⁻¹ in the IR spectrum and a singlet at δ 2.58 attributable to an SMe group. The former value is about 60 cm⁻¹ blue-shifted in the reaction, reflecting the cationic nature of the RhMoS₂ core. The S-methylation structure of 15 has further been confirmed by X-ray analysis (Figure 6 and Table 8). The total coordination geometry of 15 is comparable to that of 2b except for the S-Me group, but it should be noted that the Mo-SMe distance is considerably longer (ca. 0.07 Å) than the Mo-S(sulfido) distance, while the Rh-SMe and Rh-S(sulfido) distances are nearly the same. The SMe group is syn to the nitrosyl ligand, probably to avoid the steric repulsion with the PMe₃ ligand. Judging from the results of the alkylation of 2 and 3, π back-donation from the more electron-rich tungsten center is necessary for sufficient activation of NO toward O-alkylation. This tendency parallels well with the $v_{\rm NO}$ values and the oxidation potentials of 2 and 3.

Methylation of Pt-M' Complexes 6. Analogously to the methylation of 2a and 3a, the reaction of Pt-Mo complex

6a with 1 equiv of MeOTf yielded the S-methylated complex [(dppp)Pt(µ-SMe)(µ-S)Mo(NO)Cp*][OTf] (17) in 75% yield (eq 5).³⁶ Complex 17 shows two doublets at δ -9.1 and -13.6 with ¹⁹⁵Pt satellites in the ³¹P{¹H} NMR spectrum as well as one doublet (${}^{4}J_{PH} = 3.5 \text{ Hz}$) with ¹⁹⁵Pt satellites at δ 2.22 due to the SMe protons in the ¹H NMR, indicating the methylation of one of the bridging sulfur ligands. On the other hand, a similar reaction of Pt-W complex 6b led to a mixture of the S-methylated complex $[(dppp)Pt(\mu-SMe)(\mu-S)W(NO)-$ Cp*][OTf] (18) and the O-methylated complex [(dpp $p)Pt(\mu-S)_2W(NOMe)Cp^*][OTf]$ (19) in a ratio of 2:1 (determined by NMR spectra; eq 6).³⁵ Complex 18 has been unambiguously characterized by the ³¹P{¹H} NMR resonances at δ -9.4 and -13.8 (d with ¹⁹⁵Pt satellites), the ¹H NMR signal at δ 2.36 (br, SMe), and the IR absorption at 1602 cm⁻¹ (ν_{NO}) and **19** by the characteristic methoxyimido signal at δ 3.77 (s) in the ¹H NMR spectrum. These observations indicate that the group 10-group 6 complexes possess a lower tendency to undergo the O-alkylation of the nitrosyl ligand than the group 9-group 6 complexes, which is in full agreement with the results of the IR and cyclic voltammetry measurements. Thus, not only the tungsten center, which forms effective π back-bonding, but also the late metal center, which boosts the π -electron donation through the metal-metal bond, are essential for the O-alkylation of the ELHB nitrosyl complexes.

Reaction of 2b and 3b with HOTf. In addition to the alkylation reactions, protonation of the ELHB complexes has been attempted as an electrophilic functionalization of the nitrosyl ligand. With respect to the protonation of a terminal

Conclusion

We have synthesized a series of bis(sulfido)-bridged ELHB complexes composed of a group 6 metal nitrosyl as the reaction site and a group 9 or group 10 metal fragment as the electron pool and demonstrated that the latter unit increases the electron density on the former through the metal-metal dative bond. The 18e group 9 M^{III} center $(Cp*M(PMe_3)(\mu-S)_2)$ is shown to work as a more efficient electron donor than the 16e group 10 MII center ((diphosphine)M(μ -S)₂). Treatment of the Rh/Ir–W complexes **2b** and 3b with ROTf results in the electrophilic O-alkylation of the terminal nitrosyl ligand owing to the enormous π backdonation to the nitrosyl ligand assisted by donation from the late metal center in the ELHB core. In contrast, S-methylation takes place for the ELHB complexes with less electron-rich nitrosyl ligands. Further studies on the electrophilic functionalization of nitrosyl and related ligands at the ELHB complexes are currently underway.
