Hydrazido(2-)-complexes of Molybdenum and Tungsten formed from Dinitrogen Complexes by Protonation and Ligand Exchange

By Joseph Chatt, Alan J. Pearman, and Raymond L. Richards,* A.R.C. Unit of Nitrogen Fixation, University of Sussex, Brighton BN1 9QJ

A number of new hydrazido(2-)-complexes $[MX_2(NNH_2)(PMe_2Ph)_3]$ (A: M = Mo or W, X = CI, Br, or I) and *trans*- $[MX(NNH_2)(PMe_2Ph)_4]X$ (B: M = W) have been prepared by reaction of concentrated HX with *cis*- $[M(N_2)_2(PMe_2Ph)_4]$ in methanol. The addition of various ligands L to complexes (A) has given a series of complexes of the following types: (B: M = Mo or W), when L = PMe_2Ph; (C), $[MX(NNH_2)(PMe_2Ph)_3L]X$, when L = various pyridine bases or dimethylformamide; (D), $[M(NNH_2)(quin)(PMe_2Ph)_3]X$, when L = quinolin-8-olate ion (quin); and specifically $[WBr(NNH_2)(S_2CNMe_2)(PMe_2Ph)_2]$ (L = S_2CNMe_2) when M = W and X = Br. The (B)-type complex *trans*- $[WF(NNH_2)(PMe_2Ph)_4][BF_4]$ is obtained by treatment of *cis*- $[W(N_2)_2(PMe_2Ph)_4]$ with HF in methanol in a borosilicate-glass reaction vessel. The salts (E), $[WX(NNH_2)(PMe_2Ph)_3L]$ - $[BPh_4]$ (M = W), are obtained by reaction of Na[BPh_4] with (C; M = W) except for L = pyridine-2-thiol (2HS-py) when $[W(NNH_2)(2S-py)(PMe_2Ph)_3][BPh_4]$ results. The complexes *trans*- $[MI(NNH_2)(dpe)_2]1$ (dppe $Ph_2PCH_2CH_2PPh_2$) have been prepared by treatment of *trans*- $[M(N_2)_2(dppe)_2]$ with aqueous HI in tetrahydrofuran. Spectroscopic (i.r. and n.m.r.) data for these complexes are discussed in terms of their structures. In dichloromethane solution, complexes (A), (C), and (D) are electrochemically oxidised by one unit, but cannot be reduced.

In our investigation of the reactions of ligating dinitrogen, particularly those which may be related to nitrogenase activity, we have described its protonation and reduction to ammonia in the complexes cis- $[M(N_2)_2$ - $(PMe_2Ph)_4]$ (M = Mo or W).¹ Hydrazido(2-)-complexes of the type $[MX_2(NNH_2)(PMe_2Ph)_3]$ (A; X = Cl, Br, or I) have been shown to represent an intermediate stage in the reduction process and have been briefly

^{*a*} Calculated values in parentheses. ^{*b*} In sealed evacuated tubes, with decomposition. ^{*c*} In ca. 10^{-2} mol dm⁻³ dimethylformamide solution. ^{*d*} Cl, 11.7 (11.6%). ^{*e*} In ca. 10^{-2} mol dm⁻³ C₂H₄Cl₂ solution. ^{*f*} Contains 0.5CH₂Cl₂ of crystallisation. ^{*g*} In ca. 10^{-2} mol dm⁻³ MeNO₂ solution.

products have been investigated electrochemically to determine the effect of ligands on the ease of oxidation and reduction of the complexes and hopefully of the hydrazido(2-) ligand.

Substitution Reactions of Hydrazido(2-)-complexes.—One halide ligand in complexes (A) is labile and is readily displaced by uncharged ligands (L) such as substituted

$$trans-[M(N_2)_2(dppe)_2] + HI(aq)(excess) \xrightarrow{\text{thf}} trans-[MI(NNH_2)(dppe)_2]I + N_2 \quad (2)$$

RESULTS

Preparation of Hydrazido(2-)-complexes from Dinitrogen Complexes.—When treated with an excess of anhydrous or aqueous halogen acid (HX), under dinitrogen or *in vacuo* at 20 °C in methanol, cis-[M(N₂)₂(PMe₂Ph)₄] is converted into the hydrazido(2-)-complexes (A) [reaction (1)]. These

M-OIT

$$cis-[M(N_2)_2(PMe_2Ph)_4] + HX(excess) \xrightarrow{MCOH} [MX_2(NNH_2)(PMe_2Ph)_3] + N_2 + (A) [PMe_2PhH]X (1)$$

complexes are rather poorly soluble in the reaction solvent and are precipitated in high yields (47-88%, Tables 1 and 2). The addition of water to the mother liquor from reaction (1) precipitates a second type of hydrazido(2-)complex, $[MX(NNH_2)(PMe_2Ph)_4]X$ (B) when M = W, but not when M = Mo, in low yields (10-29%). Higher yields of (B; X = Cl or Br) are obtained by treatment of $cis-[W(N_2)_2(PMe_2Ph)_4]$ with anhydrous HX in dichloromethane.³ Some deuterio-analogues have also been prepared (Tables 1 and 2). The fluoro-complex trans-[WF- $(NNH_2)(PMe_2Ph)_4][BF_4]$ results from the reaction of cis- $[W(N_2)_2(PMe_2Ph)_4]$ with HF in methanol-diethyl ether over 14 d. The $[BF_4]^-$ anion is produced by reaction of the excess of hydrofluoric acid with the borosilicate glass walls of the reaction vessel. The complexes trans-[MI(NNH₂)- $(dppe)_2$]I $(dppe = Ph_2PCH_2CH_2PPh_2)$ have also been prepyridines or PMe_2Ph to give the cationic complexes (C) [equation (3):

$$[MX_{2}(NNH_{2})(PMe_{2}Ph)_{3}] + L \longrightarrow \\ [MX(NNH_{2})(PMe_{2}Ph)_{3}L]X \quad (3)$$
(C)

 $[L=NC_5H_5,\,NC_5H_4Me$ (2-, 3-, or 4-isomers), $NC_5H_4SH\text{-}2,$ or HCONMe2; X = Cl, Br, or I]

When $L = PMe_2Ph$ in reaction (3), complexes (A) are converted into (B). Reaction (3) for $L = HCO-NMe_2$ accounts for the high conductivity of complexes (A) in this solvent. The intensely purple cationic complexes $[W(NNH_2)(quin)(PMe_2Ph)_3]X$, (D), are obtained by treatment of complexes (A; M = W) with an excess of 8hydroxyquinoline (Hquin) [equation (4)]. The hydrogen halide generated in this reaction is taken up by the excess of basic Hquin.

$$[MX_{2}(NNH_{2})(PMe_{2}Ph)_{3}] + Hquin \longrightarrow [M(NNH_{2})(quin)(PMe_{2}Ph)_{3}]X + HX \quad (4)$$
(D)

Metathetical replacement of the anion X in (C; M = W) with Na[BPh₄] gives the complexes [WX(NNH₂)(PMe₂-Ph)₃L][BPh₄] (E) (Table 1). These are much more soluble than are (C; M = W), so much so in the case of [W(NNH₂)-(quin)(PMe₂Ph)₃][BPh₄] that it could not be isolated and was characterised spectroscopically in solution (Tables 3

⁴ J. Chatt, A. J. Pearman, and R. L. Richards, *J.C.S. Dalton*, 1976, 1520.

³ J. Chatt, G. A. Heath, and R. L. Richards, *J.C.S. Dalton*, 1974, 2074.

1769

and 4). Treatment of (C; M = W, $L = NC_5H_4SH-2$) with Na[BPh₄] not only caused replacement of one of the halide ions by PPh₄, but also dehydrohalogenation, generating the pyridine-2-thiolate ligand which presumably chelates the metal, as it does in $[Ru(NC_5H_4S-2)_2(PPh_3)_2]^{.5}$ The HX generated in this reaction is removed by the molecule of NC_5H_4SH-2 present in the crystal of (C; M = W, $L = NC_5H_4SH-2$) (Table 1) [equation (5): X = Cl, Br, or I;

$$[WX(NNH_{2})(2HS-py)(PMe_{2}Ph)_{3}]X\cdot 2HS-py + Na[BPh_{4}] \xrightarrow{CH_{2}Cl_{2}-thf} [W(NNH_{2})(2S-py)(PMe_{2}Ph)_{3}][BPh_{4}] + NaX + [2HS-Hpy]X (5)$$

 $2HS-py = NC_5H_4SH-2$, $2S-py = NC_5H_4S-2$; thf = tetra-hydrofuran].

Only in one case [equation (6)] has treatment of complexes (A) with sodium dimethyldithiocarbamate given a characterisable product.

$$\begin{bmatrix} WBr_2(NNH_2)(PMe_2Ph)_3 \end{bmatrix} + Na[S_2CNMe_2] \longrightarrow \\ [WBr(NNH_2)(S_2CNMe_2)(PMe_2Ph)_2] + \\ NaBr + PMe_2Ph \quad (6) \end{bmatrix}$$

All the above hydrazido(2-)-complexes are thermally stable, stable in the solid state for several days on exposure to air, but much less stable in solution.

Structure and Spectroscopic Properties.—The structures of $[WBr(NNH_2)(NC_6H_4Me-4)(PMe_2Ph)_3]Br$ (F)⁶ and $[W-(NNH_2)(quin)(PMe_2Ph)_3]I$ (G)⁷ have been determined by

X-ray crystallography. By analogy, complexes (C) and (D) have been assigned structures corresponding to (F) and (G) respectively. They are also 1: 1 electrolytes in solution (Tables 1 and 2). The spectroscopic properties and therefore structures of $[WX(NNH_2)(PMe_2Ph)_3L][BPh_4]$ (E) and $[W(NNH_2)(2S-py)(PMe_2Ph)_3][BPh_4]$ are also similar to that of (C).

The *mer* configuration of phosphine ligands in (D)— (F) gives rise to a pattern of two triplets and a doublet in their ¹H n.m.r. spectra ⁸ (Tables 3 and 4). Complexes (A) are poorly soluble except in solvents such as dimethylformamide (dmf), in which adduct formation occurs, as noted above. Nevertheless, in dmf solution they have a similar PMe ¹H n.m.r. pattern to (D) and (E) and so probably also have the *mer* configuration of PMe₂Ph groups. Complexes (A; M = Mo or W, X = Cl) also show two M-Cl bands in their i.r. spectra suggestive of a *cis*-chloride configuration. In view of these data and of the structures

⁵ J. D. Gilbert, D. Rose, and G. Wilkinson, *J. Chem. Soc.* (*A*), 1970, 2765; S. R. Fletcher and A. C. Skapski, *J.C.S. Dalton*, 1972, 635.

⁶ M. B. Hursthouse and M. Montevali, personal communication. of (D) and (E), a likely structure for complexes (A) is as below.

Complexes (C) and (D) show the expected two singlets (one twice the intensity of the other) in their ^{31}P n.m.r. spectra (Tables 3 and 4).

Some complications occur in the ¹H n.m.r. spectra of the complexes (C; M = W; X = Cl, Br, or I, $L = NC_5H_4Me$ -2 or -3). For $L = NC_5H_4Me$ -3 two resonances are observed for the pyridine methyl group and four triplets and a doublet for the PMe_3 groups (Table 3). This presumably arises because the pyridine methyl group, regardless of its rotation about the W-N bond, lies in two different environments depending on whether it is above or below the plane of the phosphine ligands. Thus, twice the number of resonances are observed for this complex as are seen for its analogue where $L = NC_5H_4Me-4$, where no such inequivalence can occur. The ³¹P n.m.r. spectrum of (C; M = W, $L = NC_5H_4Me-3$) shows two environments (a doublet) for the unique phosphorus atom, but only one for the mutually trans-phosphorus atoms and it is not clear why this should be. However, the ³¹P n.m.r. spectrum of the complex [WBr(NNH₂)(NC₅H₄Me-3)(PMe₂Ph)₃][BPh₄] indicates two environments for both types of phosphorus atom (Table 3) suggesting an accidental equivalence of ³¹P resonance positions in (C; M = W, $L = NC_5H_4Me-3$). The ¹H spectrum of (C; M = W, $L = NC_5H_4Me-2$) shows the normal doublet and two triplets for the PMe resonance, but the pyridine methyl group appears to show several resonances. Moreover, the ³¹P n.m.r. spectrum indicates one environment for the unique phosphorus atom and two for the trans-phosphorus atoms. The reason for these spectral properties is as yet uncertain but they may be a result of the steric interactions of the 2-methyl group.

The trans structure of the complexes (B) and trans-[WF(NNH₂)(PMe₂Ph)₄][BF₄] follows from their singlet ³¹P and ¹H (PMe) n.m.r. spectra and has already been discussed for (B; M = W, X = Cl or Br).³ The complexes [MI-(NNH₂)(dppe)₂] are also assumed to have the trans structure (see also below).

The complex [WBr(NNH₂)(S₂CNMe₂)(PMe₂Ph)₂] has a triplet PMe resonance pattern in its ¹H n.m.r. spectrum and a singlet ³¹P resonance, therefore it has *trans* phosphines and so its structure is (H).

The structural parameters of the hydrazido(2-)-group in (F), (G), trans-[WBr(NNH₂)(dppe)₂][BPh₄], and in a number of related hydrazido(2-)-complexes appear to be little affected by the variation of co-ligand at the metal (Table 5). The corresponding parameters for trans-[MoF(NNH₂)(dppe)₂][BF₄] are also very similar to those of the tungsten complexes.^{4,9}

The crystal structures of (F) ⁶ and (G) ⁷ also show that

m = Medium, w = weak, s = strong, br = broad, and sh = shoulder.

^{*a*} Hexachlorobutadiene mulls unless otherwise stated. ^{*b*} M = Mo or W, Nujol mulls between Polythene plates. ^{*c*} In deuterioanalogue. ^{*d*} Broad series of bands, Nujol mulls. there is considerable asymmetrical hydrogen bonding between the NNH_2 group and the bromide or iodide anions. A similar strong hydrogen-bonding interaction also occurs in

the analogous complexes $[MoF(NNH_2)(dppe)_2][BF_4]$ ⁹ and $[MoI\{NN(C_8H_{17})H\}(dppe)_2]I.^{10}$ This type of hydrogen bonding cannot occur in the non-ionic complexes (A) which probably explains why their i.r. spectra (Table 4) in the N-H stretching region differ from those of (B)---(G). Complexes (A) have a characteristic sharp absorption pattern, whereas (B)---(D), (F), and (G) have a very broad, largely unresolved, absorption in this region.

The NH₂ ¹H resonance positions (Table 3) of complexes (A; M = W) and (B; M = W) are also (when observed) at lower field $(6.3-7.8 \text{ p.p.m. relative to SiMe}_4)$ than those of trans- $[WX(NNH_2)(dppe)_2]Y (X = F, Cl, or Br; Y = BF_4,$ BPh_4 , ClO_4 , or PF_6) (2.90-4.0 p.p.m.)³ and those of (A; M = Mo) and (B; M = Mo) (in the range 8.11-10.10 p.p.m.) are to low field of trans-[MoF(NNH₂)(dppe)₂][BF₄] (5.11 p.p.m.).^{4,9} This chemical-shift difference is unlikely to be due to the use of unidentate phosphines in one series and chelating diphosphines in the other. We consider it to be caused by a strong hydrogen-bonding interaction in CH_2Cl_2 between the NNH₂ group and halide anion in the unidentate phosphine series. As evidence, the complexes $[WX(NNH_2)(PMe_2Ph)_3L][BPh_4]$ (L = substituted pyridines), which contain monophosphines but do not have an anion capable of strong hydrogen bonding, have their NH resonance in the same region (3.67-3.92 p.p.m.) as does $trans-[WX(NNH_2)(dppe)_2]Y.$

In this paper we also describe the preparation of the poorly soluble complexes *trans*- $[MX(NNH_2)(dppe)_2]I$, whose structure is assigned on the basis of the similarity of their i.r. spectra to those of *trans*- $[WX(NNH_2)(dppe)_2]Y^{1,3}$ and their conductivities in dmf (Tables 1 and 2). We have previously reported the preparation of their analogues $MX_2(N_2H_2)(dppe)_2 (X = Cl \text{ or } Br)^3$ and have suggested that they might be seven-co-ordinate with the N_2H_2 ligand in the

⁹ M. Hidai, T. Kodama, M. Sato, M. Harakawa, and Y. Uchida, Inorg. Chem., 1976, 15, 2694.

diazene form, NH:NH, because their NH i.r. pattern showed a large v(NH) splitting (ca. 350 cm⁻¹) as compared with trans-[WX(NNH)(dppe)₂]Y (100 cm⁻¹); also their NH resonance was at rather low field and they had low conductivity in CH₂Cl₂. In view of the data given in the previous paragraph, it now seems likely that they are salts, trans- $[MX(NNH_2)(dppe)_2]X$ (X = Cl or Br), with strong asymmetric hydrogen bonding between the NNH₂ group and X causing the shift of the NH resonance to low field and larger splitting of v(NH). One problem with this new assignment, however, is that whereas trans-[WX(NNH₂)(dppe)₂]Y and (B; M = W, X = Cl, Br, or I) have only a singlet resonance in their ³¹P spectra, $MX_2(N_2H_2)(dppe)_2$ (X = Cl or Br) show additional resonances; moreover, an asymmetric multiplet is observed at -70 °C in the ¹H n.m.r. spectrum of their ¹⁵N₂H₂ analogue.³ An X-ray structure of a member of the $MX_2(N_2H_2)(dppe)_2$ series is needed but so far suitable crystals have not been obtained. Pending a definitive structure, the hydrazido(2-)-structure, trans-[WX(NNH₂)-(dppe), X must be considered more likely than the diazene structure originally proposed.

Chemical and Electrochemical (with Dr. C. Pickett) Oxidations.—The complexes (A; M = W, X = Cl, Br, or I; M = Mo, X = Br), (B; $L = NC_5H_5$; M = W, X = Cl, Br, or I; M = Mo, X = Cl), and (D; M = W, X = Cl, Br, or I; M = Mo, X = Cl or Br) have been investigated electrochemically in dichloromethane solution, and the results are shown in Table 6. No reduction wave was observed for any complex at potentials above that of solvent discharge. All the complexes underwent oxidation by a single electron with the primary oxidation potentials for corresponding members of both the tungsten and molybdenum series having fairly similar values, the tungsten

complexes being somewhat easier to oxidise. The oxidised species observed in solution were rather unstable, especially those of molybdenum, and decomposed on attempted isolation.

¹⁰ V. W. Day, T. A. George, S. D. A. Iske, and S. D. Wagner, *J. Organometallic Chem.*, 1976, **112**, C55.

Complexes (A; X = Cl or Br) were also treated with silver nitrate or silver carbonate in an attempt to isolate oxidised hydrazido(2-)-species but in all cases quantitative evolution of dinitrogen occurred and no attempt was made to isolate the remaining metal-containing products.

DISCUSSION

The hydrazido(2-)-complexes described here and in previous papers represent the second step in the reduction of dinitrogen on molybdenum and tungsten to ammonia. In these hydrazido(2-)-complexes there is considerable multiple bonding between the ligating nitrogen atom and the metal, as demonstrated by the linearity of the M-N-N chain, and the hydrazido(2-)group acts as a four-electron donor. This multiple bonding is responsible for the stability of the M-N₂H₂ moiety, and its stability aids the protonation and reduction process. For such a process to occur the metal must have available to it a range of oxidation levels so that it can act as a π donor at the dinitrogen binding stage and a π acceptor at the hydrazido(2-)-binding stage. Transition metals to the left of the transitionmetal series with their relatively low electron affinities and tendency to multiple valency, in particular molybdenum and tungsten, are especially suited for this purpose. This accords with the generally accepted view of the function of molybdenum in nitrogenase.

The hydrazido(2—)-complexes are also capable of further protonation reactions leading to the production of ammonia and/or hydrazine, depending on the conditions. These aspects will be described in later papers.

EXPERIMENTAL

Air-sensitive materials were handled under dinitrogen or by vacuum techniques; non-condensible gases were determined by means of a Topler pump. N.m.r. spectra were recorded using a JEOL PS100 instrument (in the Fouriertransform mode for ³¹P spectra) and i.r. spectra with a Unicam SP 2000 spectrometer. Mass spectra were determined with an A.E.I. MS10 instrument and conductivities with a Portland Electronics conductivity bridge. Analyses were by Mr. A. G. Olney of the University of Sussex. The complexes cis-[M(N₂)₂(PMe₂Ph)₄] (M = Mo or W) were prepared as previously described.^{1,3} Pyridines were dried with molecular sieves before use and these and other chemicals were analytical grade and used without further purification.

Preparation of Complexes (A) and (B; M = W).—Since the methods are general, only one example for each metal is given.

 $\label{eq:Dibromotris} Dibromotris(dimethylphenylphosphine)[hydrazido(2-)]-tungsten(1v), \ [WBr_2(NNH_2)(PMe_2Ph)_3], \ and \ trans-bromotetrakis(dimethylphenylphosphine)[hydrazido(2-)]tung-$

sten(IV) bromide, trans-[WBr(NNH₂)(PMe₂Ph)₄]Br. Hydrobromic acid (2.5 cm³, 48% solution) was added with stirring under dinitrogen at 20 °C to a suspension of cis-[W(N₂)₂-(PMe₂Ph)₄] (1.7 g) in methanol (40 cm³). A rapid reaction ensued with gas evolution and formation of a red-brown solution, followed by precipitation of brown crystals of the

J.C.S. Dalton

tris(phosphine) product. The mixture was stirred for 4 h, then the solid was filtered off, washed with distilled water, methanol, and diethyl ether, and dried (10^{-3} mmHg, 20 °C).* Addition of distilled water (40 cm³) to the mother liquor precipitated orange-yellow crystals of the tetrakis(phosphine) product, which were filtered off, washed with distilled water and a little chilled methanol, then dried (10^{-3} mmHg, 20 °C). The chloro- and iodo-analogues were similarly prepared.

The above preparations were also performed *in vacuo* so that the evolved gases could be measured. Methanol (35 cm³) and hydrogen bromide (10.0 mol equivalents) were condensed *in vacuo* at -196 °C on to cis-[W(N₂)₂(PMe₂Ph)₄] (1.23 g). On warming to 20 °C, dinitrogen (37.69 cm³, 1.01 mol equivalent) was rapidly evolved with the formation of a brown-red solution followed by precipitation of brown crystals. The mixture was stirred for 4 h and then worked up as described above. The chloride analogue was similarly prepared.

Dichlorotris(dimethylphenylphosphine)[hydrazido(2-)]molybdenum(IV), $[MoCl_2(NNH_2)(PMe_2Ph)_3]$. Hydrogen chloride (15.0 mol equivalents) was condensed at -196 °C in vacuo on to cis-[Mo(N₂)₂(PMe₂Ph)₄] (0.132 g) in methanol (20 cm³) and the mixture allowed to warm to 20 °C with Dinitrogen (1.02 mol equivalent) was rapidly stirring. evolved and a red-brown solution formed during 5 min which deposited an orange-brown solid on stirring for 3 h. The solid was filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C). This complex can also be prepared using an excess of concentrated aqueous hydrogen chloride either in vacuo or under dinitrogen. The bromide and iodide analogues were prepared using an excess of the corresponding aqueous halogen acids.

Deuterio-analogues of both the tungsten and molybdenum complexes were prepared *in vacuo* using anhydrous ²HX (X = Cl or Br).

trans-Bis[1,2-bis(diphenylphosphino)ethane][hydrazido-(2-)]iodotungsten(IV) iodide, trans-[WI(NNH₂)(dppe)₂]I. Hydroiodic acid (0.4 cm³, 55% solution) was added to a suspension of trans-[W(N₂)₂(dppe)₂] (0.22 g) in methanol (35 cm³) with stirring at 30 °C in vacuo. A red-orange solution slowly formed (ca. 15 min) with evolution of dinitrogen (5.15 cm³, 1.01 mol equivalent). The solution was stirred for 18 h during which time a yellow-brown solid deposited which was filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C). The molybdenum analogue was similarly prepared.

trans-Tetrakis(dimethylphenylphosphine)fluoro[hydrazido-(2-)]tungsten(IV) tetrafluoroborate, trans-[WF(NNH_)-(PMe₂Ph)₄][BF₄]. Hydrofluoric acid (0.5 cm³, 40% solution) was added to a suspension of $cis-[W(N_2)_2(PMe_2Ph)_4]$ (0.27 g) in methanol (35 cm^3) with stirring in a borosilicate glass vessel in vacuo at 20 °C. Dinitrogen (7.42 cm³, 0.91 mol equivalent) slowly evolved with formation of a red solution (ca. 0.5 h), and this solution was stirred for another 15 h. The solution was then concentrated in vacuo to about one third its volume, diethyl ether (75 cm³) was added, and the solution allowed to stand at 0 °C for another 14 d during which time orange-brown crystals deposited. These were filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C).

Preparation of Complexes (C).—Where the method is a general one, e.g. for L = various pyridines, only one specific example is given.

Iodo(dimethylformamide)tris(dimethylphenylphosphine)-

^{*} Throughout this paper: 1 mmHg \approx 13.6 \times 9.8 Pa.

[hydrazido(2-)]tungsten(1v) iodide-dimethylformamide (1/1), [WI(NNH₂)(dmf)(PMe₂Ph)₃]I·dmf. Complex (A; M = W, X = I) (0.3 g) was dissolved in dmf (20 cm³) under dinitrogen and diethyl ether (60 cm³) was carefully added to the resulting red solution. The mixture was quickly filtered and slowly deposited red-brown crystals on standing at 0 °C which were filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C). The molybdenum analogue was similarly prepared.

Chlorotris(dimethylphenylphosphine)[hydrazido(2-)]pyridinetungsten(IV) chloride, [WCl(NNH₂)(NC₅H₅)(PMe₂-Ph)₃]Cl. Pyridine (20 cm³) was added to (A; M = W, X = Cl) (0.35 g) and the mixture stirred under dinitrogen at 20 °C until all the solid had dissolved (ca. 0.5 h). Diethyl ether (70 cm³) was then slowly added to the resulting dark red solution and the mixture was quickly filtered. On standing, the filtrate deposited red crystals which were filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C). Analogous complexes with the other substituted pyridines and those for M = Mo were prepared by a similar method.

trans-Tetrakis(dimethylphenylphosphine)[hydrazido(2-)]iodomolybdenum(IV) iodide, trans-[MoI(NNH₂)(PMe₂Ph)₄]I. Complex (A; M = Mo, X = I) (0.53 g) and PMe₂Ph (0.1 g) were stirred together in methanol (30 cm³). After a few minutes a red solution formed which was stirred for 3 h then kept at 0 °C for 16 h. Bright orange crystals deposited and were filtered off, dried (10⁻³ mmHg, 20 °C), and found to be analytically pure. The analogues for X = Cl and Br were similarly prepared.

Alternative preparation of trans-bromotetrakis(dimethylphenylphosphine)[hydrazido(2-)]tungsten(IV) bromide, trans-[WBr(NNH₂)(PMe₂Ph)₄]Br. Complex (A; M = W, X =Br) (0.17 g) and PMe₂Ph (0.03 g) were dissolved in CH₂Cl₂ (20 cm³) and the solution was stirred for 60 h. The resulting solution was filtered through Celite to remove some blue solid deposit, and diethyl ether (20 cm³) was added to the resulting clear red-brown solution. Orange crystals deposited which were filtered off and shown to be identical (i.r. spectrum and analysis) with (B; M = W, X = Br) prepared by acid treatment of cis-[W(N₂)₂(PMe₂Ph)₄] as described above.

Chlorotris(dimethylphenylphosphine)[hydrazido(2-)]-

pyridinetungsten(IV) tetraphenylborate, $[WCl(NNH_2)(NC_5-H_5)(PMe_2Ph)_3][BPh_4]$. Dichloromethane (20 cm³) and tetrahydrofuran (20 cm³) were added to a mixture of $[WCl(NNH_2)(NC_5H_5)(PMe_2Ph)_3]Cl$ (0.15 g) and Na[BPh_4] (0.1 g) and the mixture was stirred under dinitrogen at 20 °C for 18 h. The red solution was then filtered and the solvent removed *in vacuo* at 20 °C. The residue was extracted with dichloromethane (10 cm³) and diethyl ether (50 cm³) slowly added to this extract. The mixture was then quickly filtered, and left to stand at 20 °C where-upon red crystals were deposited which were filtered off, washed with diethyl ether, and dried (10⁻³ mmHg, 20 °C). The analogous complexes with various substituted pyridines were prepared in a similar manner.

Chlorotris(dimethylphenylphosphine)[hydrazido(2-)](pyridine-2-thiol)tungsten(IV) chloride-pyridine-2-thiol(1/1),

 $[WCl(NNH_2)(NC_5H_4SH-2)(PMe_2Ph)_3]Cl(NC_5H_4SH-2).$ Dichloromethane (35 cm³) was added to a mixture of (A; M = W, X = Cl) (0.31 g) and NC_5H_4SH-2 (0.31 g) and the mixture was stirred for 30 h under dinitrogen at 20 °C. The resulting dark red solution was reduced to about one

third its volume in vacuo and diethyl ether (50 cm³) was

added. The mixture was then quickly filtered and the filtrate, on standing at 20 °C, deposited dark red *crystals* which were filtered off, washed with diethyl ether, and dried $(10^{-3} \text{ mmHg}, 20 \text{ °C})$. The bromo- and iodo-analogues were similarly prepared.

Tris(dimethylphenylphosphine)[hydrazido(2-)](pyridine-2-thiolato)tungsten(IV) Tetraphenylborate, ∫W(NNH₂)- $(NC_5H_4S-2)(PMe_2Ph)_3][BPh_4]$.—Dichloromethane (20 cm³) and thf (20 cm³) were added to a mixture of $[WBr(NNH_2) (NC_5H_4SH-2)(PMe_2Ph)_3]Br \cdot (NC_5H_4SH-2)$ (0.12 g)and Na[BPh4] (0.1 g) and the mixture was stirred under dinitrogen at 20 °C for 18 h. The resulting red solution was filtered and the solvent removed in vacuo. The residue was extracted with dichloromethane (5 cm³) and diethyl ether (40 cm³) was carefully added to the extract. The mixture was quickly filtered and left to stand whereupon pale red needles were deposited which were filtered off, dried (10^{-3}) mmHg, 20 °C), and recrystallised from CH₂Cl₂-Et₂O.

Tris(dimethylphenylphosphine)[hydrazido(2-)](quinolin-8-olato)tungsten(IV) Chloride, [W(NNH₂)(quin)(PMe₂Ph)₃]-Cl.—Dichloromethane (35 cm³) was added to a mixture of (A; M = W, X = Cl) (0.32 g) and quinolin-8-ol (0.32 g) and the mixture stirred for 18 h. The resulting deep purple solution was filtered and reduced to about one third its volume in vacuo. Diethyl ether (50 cm³) was carefully added and the mixture quickly filtered. On standing the filtrate deposited very dark purple prisms of (D; M = W, X = Cl) which were filtered off, washed with diethyl ether, dried (10⁻³ mmHg, 20 °C), and recrystallised from CH₂Cl₂-Et₂O. The bromo- and iodo-analogues and the molybdenum analogues were similarly prepared.

Tris(dimethylphenylphosphine)[hydrazido(2-)](quinolin-8-olato)tungsten(IV) Tetraphenylborate, $[W(NNH_2)(quin)-(PMe_2Ph)_3][BPh_4].$ —Dichloromethane (20 cm³) and thf (20 cm³) were added to a mixture of (D; M = W, X = Br) (0.1 g) and Na[BPh_4] (0.1 g) and the mixture stirred for 18 h at 20 °C under dinitrogen. The resulting deep purple solution was filtered and the solvent removed *in vacuo*. The residue was extracted with dichloromethane (5 cm³) and the solution again taken to dryness *in vacuo*. The i.r. and ¹H n.m.r. spectra of the dichloromethane solution of the residue showed the presence of the title complex. Attempts to crystallise it were unsuccessful.

Bromo(dimethyldithiocarbamato)bis(dimethylphenylphosphine)[hydrazido(2-)]tungsten(1v), [WBr(NNH₂)(S₂CNMe₂)-(PMe₂Ph)₂].—Dichloromethane (35 cm³) was added to a mixture of (A; M = W, X = Br) (0.254 g) and Na[S₂-CNMe₂] (0.058 g, 1 mol equivalent) and the mixture stirred for 16 h at 20 °C under dinitrogen. The resulting red-brown solution was filtered and reduced to about half its volume *in vacuo*. After addition of hexane (50 cm³) the mixture was quickly filtered then allowed to stand at 20 °C when red-brown crystals were deposited. These were filtered off, washed with hexane, and dried (10⁻³ mmHg, 20 °C). No solid product was obtained if an excess of Na[S₂CNMe₂] was used.

Reactions of (A; M = W, X = Cl, Br, or I) with Ag₂-[CO₃].—The example given is for X = Cl.

Methanol (30 cm³) was condensed on to (A; M = W, X = Cl) (0.096 g) and $Ag_2[CO_3]$ (0.1 g) at -196 °C in vacuo. The mixture was warmed to 20 °C with stirring whereupon it darkened rapidly and silver metal was deposited. The mixture was stirred for another 18 h and the gas evolved was found to be dinitrogen (3.20 cm³, 0.98 mol equivalent). Further work-up of the metal-containing product was not

Reaction of (A; M = Mo, X = Cl or Br) with Ag[NO₃].— Silver nitrate (0.1 g) in water (5 cm³) was added to a suspension of (A; M = Mo, X = Cl) (0.095 g) in thf (30 cm³) and the mixture rapidly stirred. A red colour rapidly formed, dinitrogen (1.0 mol equivalent) was evolved, and silver metal was deposited. No attempt was made to isolate the molybdenum-containing product. A similar result was obtained for (A; M = Mo, X = Br).

Electrochemical Method .-- The supporting electrolyte,

kinetic cell, and solvent-purification methods have been previously described.¹¹ Cyclic voltammograms were obtained using a HiTek Instruments type DT2101 potentiostat and a Chemical Electronics type RB1 waveform generator and were recorded on a Bryans type 26000AS XY recorder.

We thank Messrs. M. E. Fakley and S. N. Anderson for technical assistance.
